NORTH COAST BIOREGION

ABOUT THE BIOREGION

The oceanography of the North Coast Bioregion (North Coast Overview Figure 1) includes waters of Pacific origin that enter through the Indonesian archipelago bringing warm, low salinity waters polewards via the Indonesian Throughflow and Holloway Currents which flow seasonally and interact with Indian Ocean waters. The Integrated Marine and Coastal Regionalisation for Australia (IMCRA V 4.0) scheme divides this Bioregion into 8 meso-scale regions: Pilbara inshore, Pilbara offshore, North West Shelf, Eighty Mile Beach, Canning, King Sound, Oceanic Shoals and Kimberley.

Ocean temperatures range between 22°C and 33°C, with localised higher temperatures in coastal waters, particularly along the Pilbara coastline. Fish stocks in the North Coast Bioregion are entirely tropical, with most having an Indo-Pacific distribution extending eastward through Indonesia to the Indian subcontinent and Arabian Gulf regions.

Coastal waters are generally low-energy in terms of wave action, but are seasonally influenced by infrequent but intense tropical cyclones, storm surges and associated rainfall run-off. These cyclone events generate the bulk of the rainfall, although the Kimberley section of the coastline does receive limited monsoonal thunderstorm rainfall over summer.

Significant river run-off and associated localised coastal productivity can be associated with cyclone events, with run-off ceasing during winter. Despite localised areas of high productivity the region is generally oligotrophic and larges areas of the coastline receive no riverine input. The entire North Coast region is subject to very high evaporation rates (3 metres per year), although the Pilbara coastline is more arid than the Kimberley, due to its lower cyclone frequency.

Other significant factors influencing coastal waters include the macro-tidal regime related to the wide continental shelf and the convergence of ocean currents. Spring tides range from greater than 11 metres along the Kimberley section of the coast down to more than 2 metres in the West Pilbara.

As a result of these factors, the generally tropical low-nutrient offshore waters can, in the few small locations with rivers, be significantly influenced by rainfall run-off and tidal mixing to generate varying water quality in different sections of the North Coast Bioregion. Along the Kimberley coastline, waters are turbid and in areas locally productive, while the Pilbara Coast with its lower run-off and lesser tidal influence has the clear waters more typical of the tropics.

The coastal geography of the various sections of the coastline also differs. The Kimberley Coast is highly indented, with bays and estuaries backed by a hinterland of high relief. Broad tidal mudflats and soft sediments with fringing mangroves are typical of this area. The eastern Pilbara Coast is more exposed than the Kimberley, with few islands and extensive intertidal sand flats. Softer sediments and mangroves occur around the river entrances. The western Pilbara coastline is characterised by a series of significant but low-relief islands including the Dampier Archipelago, Barrow Island and the Montebello Islands. Nearshore coastal waters include rocky and coral reef systems, creating significant areas of protected waters. West Pilbara shorelines also include areas of soft sediment and mangrove communities.
SUMMARY OF ACTIVITIES POTENTIALLY IMPACTING THE BIOREGION

Climate Change
Some of the key environmental trends that may be affecting ecosystems in WA include:

- Increasing frequency of El Niño/Southern Oscillation (ENSO) events;
- More years with a weaker Leeuwin Current;
- Increase in water temperature off the lower west coast of WA;
- Increases in salinity, which includes some large annual fluctuations;
- Change in the frequency and location of storms (and rainfall) affecting the lower west coast; and
- Change in the frequency of cyclones (and summer rainfall) affecting the north-west coast.

The North Coast Bioregion is predicted to have relatively minor impacts from climate change, especially in the coming decade, compared to more southerly locations (Fletcher and Santoro 2012). The variables expected to drive climate change impacts include changes in water temperature, ocean currents, winds, rainfall, sea level, ocean chemistry and extreme weather conditions.

It is apparent that climate change will impact the biological, economic, and social aspects of many fisheries, and both positive and negative impacts are expected. Climate change can influence biological systems by modifying the timing of spawning, range and distribution, composition and interactions within communities, exotic species invasions and impacts, and the structure and dynamics of communities, including changes in productivity. Species distribution shifts are the most commonly reported changes and are often the easiest to recognise and measure. Changes in the distribution of key indicator species are being monitored in a national citizen-science program (www.redmap.org.au) that the Department is collaborating in.

Commercial fishing
There are 15 different state-managed commercial fisheries that operate within the North Coast Bioregion. These fisheries target a variety of species including finfish, crustaceans, molluscs and echinoderms (North Coast Overview Figure 2). The principal commercial fisheries in the North Coast Bioregion focus on tropical finfish, particularly the high-value emperors, snappers and cods that are taken by the Pilbara trap, line and trawl fisheries and the Northern Denserial Scalefish (trap and line) Fishery. The typical catch is in the order of 3,000 t annually, making these fisheries, at an estimated annual value of at least $12 million, the most valuable finfish sector in the State. A number of other finfish fisheries operate in the Bioregion, including near-shore beach seining and gillnetting for barramundi and threadfin salmon (the Kimberley Gillnet and Barramundi Managed Fishery) and surface trolling for Spanish mackerel (the Mackerel Managed Fishery).

Another significant commercial fishery in this Bioregion is based on the collection of pearl oysters (Pinctada maxima) for use in the aquaculture production of pearls (see below). These are collected from the fishing grounds primarily off the Eighty Mile Beach, with smaller catches being taken around the Lacepede Islands (north of Broome).

The North Coast Bioregion also has a number of small, limited-entry trawl fisheries for prawns, producing about 700 t annually, valued at around $10 million. These fisheries include the Onslow, Nickol Bay, Broome and Kimberley Prawn Managed Fisheries (collectively referred to as the North Coast Prawn Managed Fisheries). Two small trap-based crab fisheries also exist in the Bioregion, targeting blue swimmer crabs in the Pilbara (the Pilbara Developing Crab Fishery) and mud crabs in the Kimberley (the Kimberley Developing Mud Crab Fishery). Sea cucumbers (also known and bêche-de-mer or trepang) are collected by hand by divers and waders throughout the Kimberley region as part of the Bêche-de-Mer Fishery. Catches are mainly comprised of two species, sandfish (Holothuria scabra) and redfish (Actinopyga echinites). The Trochus Fishery is a small fishery based on the collection of a single target species, Tectus niloticus from King Sound and the Buccaneer Archipelago. This fishery is operated by the Bardi Jawi and Mayala Aboriginal Communities, who have been collecting trochus in this area since the 1960s.

A traditional artisanal fishery also exists in an area around Roti Island, known as the MOU box. The MOU Box is an area within the Australian EEZ over which there is a bilateral agreement between Australia and Indonesia. The MOU allows Indonesian fishers to fish using traditional methods within Australian waters and has been operation al since 1974.

Recreational Fishing
Recreational fishing is experiencing significant growth in the North Coast Bioregion, with a distinct seasonal peak in winter when the local population is swollen by significant numbers of metropolitan and inter-state tourists travelling...
through the area and visiting, in particular, the Onslow, Dampier Archipelago and Broome sections of the coastline. This may have been added to by the increased recreational fishing resulting from those involved in the construction or operation of major developments in this region. Owing to the high tidal range, much of the angling activity is boat-based, with beach fishing limited to periods of flood tides and high water. The numerous creek systems, mangroves and rivers, and ocean beaches provide shore and small boat fishing for a variety of finfish species including barramundi, tropical emperors, mangrove jack, trevallies, sooty grunter, threadfin, cods and catfish, and invertebrate species including blue swimmer crabs, mud crabs and squid (North Coast Overview Figure 3). Offshore islands, coral reef systems and continental shelf waters provide recreationally caught species including tropical snappers, cods, coral and coronation trout, sharks, trevally, tuskfish, tunas, mackerels and billfish.

Aquaculture

Aquaculture development in the North Coast Bioregion is dominated by the production of pearls from the species *Pinctada maxima*. An overview of aquaculture activities in the Bioregion is detailed in North Coast Overview Figure 4. A large number of pearl oysters for seeding is obtained from wild stocks and supplemented by hatchery-produced oysters, with major hatcheries operating at Broome and the Dampier Peninsular. Pearl farm sites are located mainly along the Kimberley coast, particularly in the Buccaneer Archipelago, in Roebuck Bay and at the Montebello Islands. Developing marine aquaculture initiatives in this region include growing trochus and barramundi. Marine production of barramundi is focussed in Cone Bay where an operator is currently licensed to produce 2,000 tonnes per annum. Establishment of an aquaculture zone (further described under the regional aquaculture research and development section in this chapter) has been funded in this area in which the Department of Fisheries will secure strategic environmental approvals, thereby streamlining the approvals processes for commercial projects and providing an “investment ready” platform for prospective investors. This is expected to lead to the development of further aquaculture operations in the region. A company developing a project culturing marine microalgae for the production of bio-fuels, omega-3 lipid and protein biomass previously established a demonstration facility near Karratha. The company is currently assessing alternative sites for the project. A focus of aquaculture development is provided by the Department of Fisheries’ Broome Tropical Aquaculture Park, which houses a commercial pearl oyster hatchery and the Kimberley Training Institute aquaculture training facility. An indigenous project at One Arm Point operates a marine hatchery that focuses on a variety of ornamental and edible marine species.
Tourism

The marine tourism industry has experienced significant growth within the North Coast Bioregion, particularly along the Kimberley coast in recent decades. As coastal access is limited, tourists generally access the coast by boat from major population centres, such as Broome and Wyndham. Activities include charter fishing, diving, snorkeling, whale, turtle and dolphin watching, and sightseeing cruises. Sites of greatest interest to tourists include places to fish, areas for sightseeing and secluded locations for general relaxation. Luxury cruises take tourists along the coastline and increasingly out to isolated coral atolls for fishing and diving. Primary dive locations include the Rowley Shoals, Scott Reef, Seringapatam Reef, Ashmore Reef and Cartier Island.

Shipping and Maritime Activity

There are three major ports in the North Coast Bioregion: Broome, Dampier and Port Hedland (North Coast Overview Figure 5). The Port of Broome provides vital support for the Browse Basin offshore oil and gas industry. Other business includes livestock export, cruise liner servicing, coastal trading vessels, pearling, fishing and tourism charters. The Port of Dampier services both the land-based iron ore reserves and the offshore gas fields of the Carnarvon Basin. The Port of Port Hedland is the world’s largest bulk exporter, with 99% of the total cargo volume constituting exports. The port primarily exports iron ore, along with salt, livestock and petroleum products. There are eight other non-port authority ports in the North Coast Bioregion. In general, these ports and related export facilities are operated by resource companies. Most handle raw bulk commodity exports such as iron ore, crude oil and salt. An increase in shipping and port expansion associated with growth of the resources sector has potential implications for the marine environment. Potential threats include loss or contamination of marine habitats as a result of dredging and sea dumping, oil spills, interactions between vessels and listed species and the introduction of marine pests.

Oil and Gas Activity

Offshore oil and gas is a large and rapidly growing industry in the North Coast Bioregion. Within the Bioregion, the Northern Carnarvon, Browse and Bonaparte Basins hold large quantities of gas, and multiple projects are in various stages of development, production and exploration (North Coast Overview Figure 5). The main disturbances associated with oil and gas exploration and production include noise pollution from seismic surveys, potential for fish movement/impact arising from seismic surveys, disturbance to the marine habitat through drilling and/or dredging activities, release of produced formation water, shipping and transport activities and oil spill accidents.

ECOSYSTEM MANAGEMENT

A variety of measures have been implemented to manage the potential impact of activities on the ecosystem within the North Coast Bioregion. These include:

Climate Change

Extensive work has been undertaken as part of a three-year FRDC-funded project (Caputi et al. 2015a,b) that assessed the effects of climate change on the marine environment and key fisheries, as well as management implications. The first phase of the project was to understand how environmental...
factors, such as water temperature and salinity, affect fish stocks in Western Australia based on available historical data. The second phase was to look at historical trends and possible future scenarios of WA marine environments using climate model projections. Lastly, existing management arrangements were reviewed to examine their robustness to climate change effects and new management policies will be developed in consultation with stakeholders to deal with climate change effects on fish stocks. Although these studies focused on Bioregions more susceptible to increases in SST to the south, there were no documented effects of climate change occurring on the species selected (Caputi et al. 2015a,b). However, if anecdotal information is quantified on a southward shift in the range of Narrow-Barred Spanish Mackerel then it is possible that the total biomass of this species in Western Australia will increase due to various factors associated with breeding and availability of suitable habitats (Caputi et al. 2015b).

The Department of Fisheries’ Research Division’s Biodiversity and Biosecurity Branch also recently completed a pilot project aimed at establishing resource condition monitoring protocols for the Pilbara and Kimberley. The establishment of standardised long term resource monitoring programs is fundamental to understanding and thus mitigating the impacts of climate change on marine resources. The project focussed on an extensive survey of the research literature relating to the coastal and marine environments in the Pilbara and Kimberley. The review of the literature has highlighted those areas of research that are lacking from the region. The vast and remote coastline of the region dictates that remote sensing (satellite imagery and aerial photography) will be the primary tool for resource condition monitoring. The project concentrated on developing remote sensing as a monitoring tool, and developing a suite of resource condition indicators that accurately portray the health of the numerous marine and coastal environments, and set benchmarks for which to assess environmental change, within the Pilbara and Kimberley. The Department is also a key collaborator in the National RedMap (Range Extension Database & Mapping project) project (www.redmap.org.au) which uses a citizen-science approach to document range extensions of a number of key identified climate-change affected species. Understanding shifts in populations is likely to be increasingly important to adaptive fisheries management.

### Spatial Closures

Extensive fisheries closures in coastal and most offshore waters have been introduced to manage finfish trawling by Australian vessels (North Coast Overview Figure 6). However, trawling is still permitted in a small number of limited locations, which in total represent less than 11% of the shelf waters (North Coast Ecosystem Management Table 1; see specific commercial trawl fishery reports elsewhere in this volume). This activity is carefully managed to ensure that impacts are acceptable. The trawling is subject to Ecologically Sustainable Development (ESD) requirements in accordance with the Commonwealth Government ‘Guidelines for the Ecologically Sustainable Management of Fisheries’ under the Environment Protection and Biodiversity Conservation Act 1999. The extent of these areas means that 41% of the entire shelf region of the North Coast Bioregion could be classified as a marine protected area with an IUCN category of IV or higher (as per Dudley, 2008 and Day et al 2012); North Coast Ecosystem Management Table 1).

### NORTH COAST ECO SYSTEM MANAGEMENT TABLE 1

In addition to these habitat related marine protected area closures, the Bioregion has a number of other marine protected areas with various management objectives, summarised in North Coast Overview Figure 7. These include the Montebello and Barrow Islands and the Rowley Shoals proclaimed under the Conservation and Land Management Act 1984 (see North Coast Ecosystem Management Figure 2), and closures to fishing under section 43 of the Fish Resources Management Act 1994 at Point Samson and the wreck of the Kumunuva Samson II (Delambre Reef). The Department of Fisheries has also participated in the marine conservation reserve planning process in this Bioregion and has established baseline and ongoing monitoring and research to underpin ecosystem management. There is considerable interest in developing further marine protected areas within the Kimberley region, and the State Government is developing management plans, Indigenous Land Use Agreements (ILUA) and zoning arrangements for marine protected areas at Eighty Mile Beach, Roebuck Bay, Horizontal Falls and the North Kimberley. The proposed Dampier Archipelago marine conservation reserves are still under consideration by Government. The Department continues to work closely with relevant agencies and stakeholders to develop strategies to minimize environmental impacts in the marine environment. This includes participation in the Kimberley Science and Conservation Strategy developed with the Department of Parks and Wildlife (DPAW) and collaboration on relevant Western Australian Marine Science Institute (WAMSI) Kimberley Marine Research Program projects.

The Commonwealth Government has also undertaken a Marine Bioregional Planning process for Commonwealth waters between Shark Bay and the Northern Territory border. The federal minister for the environment had announced a final reserve network proposed for the North-West which spans the North Coast and Gascoyne Bioregions but this is under review by the current Government.
Management of Commercial Fisheries

There is a high degree of ecosystem management and protection for the ecological assets that are located within the North Coast Bioregion. Each of these fisheries operates under a specific management plan, the arrangements of which are implemented through the legislative framework provided by the Fish Resources Management Act 1994 (FRMA). The FRMA and the management plan for each fishery adhere to arrangements established under relevant Australian laws, with reference to international agreements that require conservation of all ‘fish’ and fisheries resources (which through the definition of fish includes nearly all aquatic organisms).

In WA, comprehensive controls on fishing were first introduced in the 1960s and now apply to all commercial fisheries. These controls are designed to ensure that all catches are kept at sustainable levels, which in turn requires that the annual catch is a relatively small proportion of the overall stock biomass. This approach maintains relatively high biomass levels for all harvested species compared to their unfished situation and therefore ensures that all trophic levels are being kept at relatively high levels of abundance. These management requirements have significantly reduced the risk of such trophic flow-on effects from occurring, and none are evident in the long-term trends in fish catches.

Strict limits on the use of fishing gear that can result in unwanted interactions with non-targeted species provide similar protection for bycatch and listed species and thus, biodiversity generally. Examples of controls that operate in at least one fishery within the Bioregion include:

- Limited entry;
- Variable spawning/size season closures (areas closed or opened depending upon catch rates and sizes of invertebrates);
- Permanent and seasonal area closures to preserve sensitive habitats that are essential nursery areas;
- Temporal general closures;
- Primary and secondary bycatch reduction devices (BRDs) and excluder devices;
- Total Allowable Catch limits;
- Target catch ranges;
- Minimum commercial size limits;
- Protection of berried females (invertebrates); and
- Monitoring of fishing activities using the Vessel Monitoring System (VMS).

The State is currently employing a Bioregional approach to the pre-assessment of all its fisheries for potential third party certification according to the sustainability criteria developed by the Marine Stewardship Council (http://www.msc.org/). The progression of a number of fisheries to full certification is underway. This process will ensure independent assessment of the sustainability and effective management of assessed fisheries to an internationally recognised standard.

Management of Recreational Fisheries

Recreational fishing in the North Coast Bioregion was managed via a Bioregional-specific management strategy from 2003 until Statewide management was largely reintroduced in 2013. This strategy consists of a set of bag, possession and size limits, permitted gear types and seasonal and area closures implemented under the Fish Resources Management Act 1994. All recreational fishing activities, including those of the charter sector, are subject to the closures associated with marine protected areas detailed above. In 2010, a statewide recreational ‘fishing from boat’ licence was also introduced. A number of recreational fishing surveys have been undertaken, including a recent statewide recreational fishing from boat survey in 2011/12 (Ryan et al., 2013).1 The results of such surveys are used to estimate recreational catch and effort of targeted finfish and crustaceans. The results of such surveys are used to maintain a sustainable Bioregional-specific management strategy. A second biennial survey is currently being completed.

Compliance and Community Education

Significant effort is put into ensuring adequate compliance with commercial and recreational fishing regulations. This includes at sea and aerial patrols to ensure closed seasons, closed areas, and operational rules are being adhered to. The use of VMS on commercial vessels also helps the Department monitor vessel location and speed, thus increasing compliance with closures while decreasing the need for untargeted patrol activities.

Biosecurity Risk Management

The Department is working closely with the Commonwealth Government and other jurisdictions to develop and implement the National System for the Prevention and Management of Marine Pest Incursions that will minimise the biosecurity risks associated with increased shipping in the Pilbara and Kimberley regions. Within WA, this is currently achieved through the Fish Resources Management Act 1994 and the Biosecurity and Agriculture Management Act 2007. The Department is the lead agency with responsibility for marine biosecurity in the State. The increase in international shipping movement and dredging activity associated with resource development in the Northern Bioregion is considered to present a high risk to the marine environment because of the potential for the introduction of non-indigenous marine organisms (including animals, plants, pathogens and diseases) into WA’s coastal environment. Introduced marine pests can predate on native and farmed species, out-compete natives for space and food, alter nutrient cycle, lead to a loss of diversity in local species, cause human health impacts, negatively affect commercial fish and seafood species, negatively affect amenity and recreational activities and reduce the fuel efficiency for all vessel types. With increasing human population and associated travel, transport

1 Ryan et al., 2013. An integrated system to survey boat-based recreational fishing in Western Australia 2011/12, December 2013. Fisheries Research Report 249.

STATUS REPORTS OF THE FISHERIES AND AQUATIC RESOURCES OF WESTERN AUSTRALIA 2014/15 163
and trade, the risk of introducing new species is likely to grow. Biosecurity risks associated with commercial vessel movements are managed through the routine monitoring of ports for marine pest species and management of risk associated with biofouling on commercial vessels utilizing state waters. Oil and gas related developments in the region have their own ministerial guidelines to ensure marine and coastal resources are protected. These developments undertake ‘proof of freedom’ pest monitoring to ascertain they have no pests present.

The Marine Biosecurity Research and Monitoring Group implements a range of monitoring and research activities in the bioregion focussed on detection of introduced marine pests (IMPs) at high risk locations and vessel risk analyses. Early detection of IMPs is vital if any attempt at eradication or other management strategies are to be successful. Further details for these projects may be found in the “Introdued Pests Status Report” at the end of this section and also in the Appendix section entitled “Activities of the Marine Biosecurity Research Group during 2014/15”.

**Management of Aquaculture**

The main focus of the Department of Fisheries in the North Coast Bioregion continues to be on the regulation of the pearling industry based on the silver lip pearl oyster (*Pinctada maxima*) and the barramundi finfish aquaculture sector. The Department manages risks associated with aquaculture which include disease, the potential introduction of marine pest species and the impact of escapes. In recognition of the positive contribution aquaculture can have on wild stock sustainability, the economy and regional communities, the Department has recently engaged in a project to establish an aquaculture zone in the Kimberley with the aim of encouraging investment in sustainable finfish aquaculture through providing streamlined approval processes. The Department manages the impact of aquaculture via implementation of a comprehensive suite of conditions associated with aquaculture licences and through the legislative framework provided by the *Fish Resources Management Act 1994* (FRMA).

**Management of Tourism**

The Department has responsibility to manage the impacts of tourism where they may have a direct impact on fish resources. This is achieved through the measures detailed above aimed at managing recreational fishing. In addition to this regulation, formal management arrangements were also introduced for the charter sector in 2001 which include a ‘cap’ on the total number of operators statewide. Licensed operators that are engaged in extractive fishing are required to submit trip-by-trip catch and effort records. Otherwise, charter fishing is generally subject to the same regulation as private recreational fishers.

**Management of Oil and Gas Impacts**

Marine habitats within the North Coast Bioregion of Western Australia are experiencing increasing pressure through a range of activities but most notably as a result of increased resource development activity that is occurring in the area. The Department continues to engage with the Environmental Protection Authority through the environmental impact assessment process by providing advice on individual development proposals, which if implemented, have the potential to have an adverse impact on the marine environment. These include new (and upgraded) port developments in the Pilbara region, as well as offshore and nearshore oil and gas extraction projects in the Kimberley and Pilbara region. Major developments recently assessed for which the Department has played a key role include the Gorgon Gas Development at Barrow Island, and the proposed Kimberley LNG processing site. The Montara oil spill that occurred in this region highlights the potential risks to this area from oil and gas production.

**ECOSYSTEM MONITORING AND STATUS**

In order to assess the adequacy of management arrangements aimed at ensuring sustainability of the ecological assets within the North Coast Bioregion, the Department must identify and monitor trends in the condition of these resources. This is achieved through application of an Ecosystem Based Fisheries Management (EBFM) framework (*Fletcher, et al., 2010*) (see How to Use section for more details) to identify, in a hierarchical manner, the key ecological resources that require ongoing monitoring and assessment.

These key ecological assets identified for the North Coast Bioregion are identified in Figure 8 and their current risk status reported on in the following sections.

---

External Drivers

External factors include factors impacting at the Bioregional-level that are likely to affect the ecosystem as whole and may not fall within the direct control of Fishery legislation (e.g. climate change). An understanding of these factors, which are typically environmental (cyclones, ocean currents) is necessary to fully assess the performance of the ecological resource. The main external drivers identified with potential to affect the North Coast Bioregion include climate, introduced pests and diseases and oil and gas development activities.

Climate

<table>
<thead>
<tr>
<th>External Driver</th>
<th>Current Risk Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Climate</td>
<td>LOW</td>
</tr>
</tbody>
</table>

The North Coast Bioregion is predicted to have relatively minor impacts from climate change, especially in the coming decade, compared to more southerly locations. Cheung et al. (2012) examined the effects of climate change on the distribution of 30 species of marine fish and invertebrates along the Western Australian coast. Important North Coast Bioregion species included western king prawns (*Penaeus latisulcatus*), blue swimmer crabs (*Portunus armatus*), redthroat emperor (*Lethrinus miniatus*), Spangled emperor (*Lethrinus nebulosus*), common coral trout (*Plectropomus leopardus*), goldband snapper (*Pristipomoides filamentosus*), rosy snapper (*Prestipomoides filamentosus*), and scaly mackerel (*Sardinella lemuria*). Changes in distribution were simulated using outputs from both a Regional Oceanographic Model and a Global Circulation Model. Results indicated a median shift of around 19 km per decade towards higher latitudes and 9 m deeper per decade by 2055 relative to 2005. As a result of these shifts, the temperate coast of Western Australia is expected to experience a ‘tropicalisation’ of the marine community, with an increased dominance of warmer-water species, resulting in shifted fishing grounds and unexpected trophic effects (Cheung et al. 2012).

Introduced Pests and Diseases

<table>
<thead>
<tr>
<th>External Driver</th>
<th>Current Risk Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced Pests and Diseases</td>
<td>HIGH</td>
</tr>
</tbody>
</table>

The increase in international shipping movement and dredging activity associated with resource development in the North Coast Bioregion is considered to present a high risk to the marine environment because of the potential for the introduction of non-indigenous marine organisms, including animals, plants, pathogens and diseases. The Department implements a range of monitoring and research activities in the Bioregion, focussed on early detection of potential marine pests. Further details for these projects may be found in the “Introduced Pests Status Report” at the end of this section and also in the Appendix section entitled “Activities of the Marine Biosecurity Research Group during 2014/15”.

Oil and Gas Development Activity

<table>
<thead>
<tr>
<th>External Driver</th>
<th>Current Risk Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oil and Gas Development</td>
<td>LOW</td>
</tr>
</tbody>
</table>

While there are a number of specific oil and gas related offshore developments that are proposed in this region, at the overall ecosystem level there is only a low risk that the
ecosystem will be altered measurably. Some of the risks identified (e.g. increased turbidity) are being examined under WAMSI 2 projects. In addition, State and Commonwealth marine parks, including totally protected zones, are currently planned or in place.

**Ecosystems and Habitats**

Coastal geography is extremely variable within the North Coast Bioregion and its identified meso-scale ecosystems include a range of key habitats in depths of less than 40 m (where the vast majority of relevant fisheries resources are located and fishing activities are undertaken in this Bioregion) which include:

- **Mangroves**: Mangroves occur throughout the Bioregion, and within the Kimberley, are considered to be very well developed and relatively pristine. The mangrove communities of Roebuck Bay and Eighty Mile Beach have been listed as Ramsar Wetlands of International Significance mainly due to the numbers of migratory wading birds they support.

- **Seagrasses**: Seagrasses are mainly tropical species. Twelve species have been identified throughout the North Coast Bioregion, including one endemic species (*Cymodocea angustata*). Within the Bioregion, seagrasses are generally found in shallow water environments near the mainland coast and offshore reefs and shoals.

- **Algae**: Algal growth is restricted by the limited presence of hard substrates on the North West Shelf. Throughout the Kimberley, the effects of strong tidal currents and high turbidity result in low macroalgal diversity. Surveys in the Kimberley have identified 72 species of macroalgae in the southern Kimberley and 90 species (not including coralline algae) in the northern Kimberley, most of which are widespread tropical taxa.

- **Sponges and Filter-Feeding Communities**: Sponges are found from tidal areas to the deep waters of the Abyssal Plain and generally occur as part of a mixed filter-feeding community. Species richness varies considerably throughout the Bioregion, with both relatively low-diversity communities (< 25 species, e.g. Rowley Shoals) and exceptionally rich communities (> 250 species, e.g. Dampier-Port Hedland regions). Sponge communities throughout the Bioregion are also broadly different. For example, a study by the Western Australian Museum found more than half the sponges identified at Mermaid, Scott and Seringapatam Reefs, Browse Island and the Rowley Shoals were unique to a single reef (WAM, 2006).

- **Coral Reefs**: Coral reefs in the Bioregion fall into two general groups: the fringing reefs around coastal islands and the mainland shore and large platform reefs, banks and shelf-edge atolls on the mid and outer shelf. North of Cape Leveque, the Kimberley supports extensive nearshore reef systems. Areas of fringing reef development include islands in the Buccaneer Archipelago, the Heyward island group, islands of the Bonaparte Archipelago and off mainland shores of Cape Voltaire and Cape Bougainville. Coral diversity is typically high, with surveys of the Buccaneer Archipelago having recorded 280 species of coral from at least 55 genera. Coral reefs are also well developed around offshore island such as Ashmore, Cartier, Hibernia, Seringapatam and Scott Reefs, Browse Island and the Rowley Shoals.

- **Sand/Mud**: Embayments along the Kimberley are known to have extensive muddy tidal flats and the majority of the offshore area is dominated by soft sediment seabeds, which are mainly sand/mud with occasional patches of coarser sediments.

In depths beyond 40 m, ecosystems include hard- and soft-bottom benthic communities, sand banks and pelagic communities. Given the low levels of activities in these depths, there is little detailed information on these environments.

A high level of protection of the ecosystems and habitats within the North Coast Bioregion is ensured based on the limited area of the Bioregion that is available to commercial trawl fishing activity (North Coast Bioregion Overview Figures 6 and 7). The Department manages commercial, charter, recreational and indigenous fishing in State coastal waters (generally to 3 nm). By way of the Offshore Constitutional Settlement 1995 (OCS) agreement between the State and Commonwealth Governments, control is also given to WA for most fisheries which operate out to 200 nm from the coast (except for trawling where WA’s jurisdiction is limited to the 200 m isobath). If the areas that are not trawled is taken into account, 89 % of statewide benthic habitats out to the 200 m isobath are, in practical terms, fully protected and may never have been trawled (North Coast Ecosystem Management Table 1). In addition to fisheries-related closures, the North Coast Bioregion has a number of marine protected areas described under the preceeding “spatial closures” section.

The Department identifies and monitors trends in the condition of ecosystems and their associated habitats to ensure the long term sustainability of both these key ecological assets and the fisheries that depend on them.

The Kimberley Nearshore Ecosystem (KNE) includes coastal waters to 20 m depth from Cape Missiessy at the northern end of Eighty Mile Beach (19° 03’ S; 121° 31’ E) to the Northern Territory border. This ecosystem includes the nearshore sections of five of the IMCRA-identified
Bioregions: Canning, King Sound, Kimberley, Cambridge-Bonaparte and Bonaparte Gulf.

Ecosystem

Estuarine (non-fishing)
With the onshore developments that are proposed in this area, while some specific areas may be locally impacted, these still only pose a low risk to the overall nearshore/estuarine ecosystem of this Bioregion.

Marine
The main fisheries in the region are selective and based on trap (Kimberley Demersal Mud Crab Fishery; KDMCF), gillnet (Kimberley Barramundi Gillnet Fishery; KBGF) and hand collection (Kimberley Beche-de-Mer Fishery; KBFM). The current level of fishing by all methods in the Kimberley Nearshore Ecosystem does not appear to have noticeably affected the trophic systems and/or community structure of the ecosystem. The majority of catch from each fishery is comprised of the main target species, and catches of these species have remained relatively stable throughout the history of each fishery, excepting where effort has dropped due to market demands (i.e. the Trochus Fishery). The target species for each fishery have wide distributions beyond the fishing areas, and their removal at current rates is unlikely to seriously or irreversibly alter community structure.

Habitat

Estuarine (non-fishing)
The main risks to nearshore habitats come from oil and gas resource development and the expansion of port facilities, plus periodic cyclones.

Marine
The main fisheries in the region are selective and based on trap (Kimberley Demersal Mud Crab Fishery; KDMCF), gillnet (Kimberley Barramundi Gillnet Fishery; KBGF) and hand collection (Kimberley Beche-de-Mer Fishery; KBFM) and thus constitute a minimal disturbance to benthic habitats. The majority of these fishing activities occur in mud/sand habitats in estuaries, tidal creeks and embayments. In general, mud/sand areas are less affected by disturbances than sensitive habitats, i.e. corals and seagrasses. In the case of the KDMCF, fishing with traps results in limited habitat disturbance, and the large mesh size used prevents the capture of benthic organisms. The sheltered, shallow mangrove environment is protected from wind and waves, and there is minimal dragging of traps on the sea bottom during retrieval. Fishing activities associated with the KBGF mainly take place over sandy habitats in nearshore, shallow waters, which are subject to extreme tidal currents and associated effects. Gillnets have a relatively low seafloor impact, and the Fishey is considered to be a low risk to benthic habitats. Fishers in the BDMF catch bêche-de-mer by diving or wading, with collection by hand only. Divers collect bêche-de-mer as they drift over the bottom and are careful not to contact the seabed during fishing activities. The spatial distribution of all fishing activities are also managed through the use of seasonal and area closures to protect sensitive habitats.

</table>

The Pilbara Nearshore Ecosystem (PNE) is defined as coastal waters to 20 m depth from Cape Mississeny at the northeastern end of Eighty Mile Beach (19° 03’ S; 121° 31’ E) to the North Coast Bioregion boundary just south of Onslow (114° 50’ E). This region includes the nearshore sections from three IMCRA-identified Bioregions: Pilbara Inshore, Pilbara Offshore and Eighty Mile Beach.

Ecosystem

Estuarine (non-fishing)
With the onshore developments that are proposed in this area, while some specific areas may be locally impacted, these still only pose a low risk to the overall nearshore/estuarine ecosystem of this Bioregion.

Marine
The current level of removal of all retained species is considered to have only minor impacts on the trophic structure of the Pilbara nearshore ecosystem. The current level of fishing by all methods in the Pilbara nearshore ecosystem does not appear to have noticeably affected the trophic systems and/or community structure of the ecosystem. The majority of catch from each fishery is comprised of the main target species, and catches of these species have remained stable throughout the history of each fishery. The majority of the retained catch for both the Onslow Prawn Managed Fishery (OPMF) and the Nikol Bay Prawn Managed Fishery (NBPMF) is comprised of various prawn species, with target prawn species comprising on average 80% of the total catch in the OPMF and 74% in the NBPMF for the past 10 years. None of the main target species are known to be involved in any strong ecological interactions and their removal at current rates is unlikely to seriously or irreversibly alter community structure. Prawns have a very high natural mortality and turnover rate, such that a large percentage of the yearly recruits are naturally removed from the system (either by death or predation) by the end of the fishing season regardless of fishing activities. As a result of this naturally high variation, the effect of removing prawns at current levels through fishing would be minimal. Additionally, the management of spatial and seasonal closures ensures that an adequate spawning stock of all species of prawns survive to reproduce recruits for the subsequent season.
The main risks to nearshore habitats come from oil and gas resource development and the expansion of port facilities, plus periodic cyclones.

Ecosystem

The majority of fishing activities take place over mud and sand habitats. Trawl activities are considered to have the highest relative impact of the methods used within the Pilbara nearshore ecosystem which also includes low impact activities of trap (eg Pilbara Developing Crab Fishery) and hand collection (eg Pearl Oyster Managed Fishery) based fisheries. However, the spatial extent of trawling activities is small, and there are a variety of measures in place to manage any impacts. Both the Onslow Prawn Managed Fishery (OPMF) and the Nickol Bay Managed Prawn Fishery (NBMPF) fisheries use otter trawl systems, which have been demonstrated to have the least impact of all forms of trawling. Within Onslow Area 1, a study of biodiversity found no significant differences in the fish and invertebrate abundance, species richness, evenness or diversity between trawled and untrawled areas (Kangas et al. 2007). These findings indicate that trawling does not have a significant impact on the faunal community, which also suggests that trawling has not significantly impacted on the benthic habitats where trawling occurs. The trawl grounds of the OPMF and the NBMPF are largely separated, on a geographical and depth basis, from other sensitive habitats, such as coral and sponge communities. Trawlers focus their activities in areas of high western king, brown tiger and/or banana prawn abundance, which is typically mud and sand areas outside of dense soft coral/sponge habitats.

Kimberley Inshore (Shelf)

<table>
<thead>
<tr>
<th>Ecosystem/habitat</th>

<tbody>
<tr>
<td>Kimberley inshore ecosystem</td>
<td>Marine</td>
<td>LOW</td>
</tr>
<tr>
<td>Kimberley inshore habitat</td>
<td>Marine, Sand/Mud Sponge, Reef</td>
<td>LOW</td>
</tr>
</tbody>
</table>

The Kimberley Inshore Ecosystem comprises the broad North West Shelf area off the Kimberley coast and includes all waters seaward of the 20 m depth contour to depths of 250 m and includes a number of mid-shelf islands. The Kimberley Inshore Ecosystem includes sections of five IMCRA Bioregions: Canning, Kimberley, Cambridge-Bonaparte, Bonaparte Gulf and the northern section of the North West Shelf.

Ecosystem

While there are a number of specific oil and gas related offshore developments that are proposed in this region, at the overall ecosystem level there is only a minor risk that the ecosystem will be altered measurably. Assessments of the community structure and trophic level of all commercially caught fish species in the Pilbara and Kimberley regions over the past 30 years found no evidence that there have been any systematic changes. Therefore, there is no indication that the fish faunas have been impacted by the development of the scalefish fisheries to the extent that ecosystem function in the Kimberley Inshore Ecosystem has been affected (Hall and Wise 2011). The majority of catch from each fishery is comprised of the main target species, and catches of these species have relatively remained stable throughout the history of each fishery, excepting where effort has dropped due to economic factors (i.e. the Broome Prawn Managed Fishery). None of the main target species are known to be involved in any strong ecological interactions, and their removal at current rates is unlikely to seriously or irreversibly alter community structure.

Habitat

Trawl activities are considered to have the relatively highest habitat impacts of the methods used within the Kimberley Inshore Ecosystem; however, the majority of trawling takes place of sand/mud bottom habitats, and only occurs over a small area of the ecosystem with most of this region being closed to trawling. Additionally, the spatial extent and intensity of fishing activities in both the trawl and trap (e.g. the Northern Demersal Scalefish Managed Fishery) fisheries are monitored annually using daily logbooks and VMS. Prawn trawling by the Broome Prawn Managed Fishery and the Kimberley Prawn Managed Fishery occurs predominantly over mud and sand habitats and both fisheries use otter trawl systems, which have been demonstrated to have the least impact of all forms of trawling. The spatial distribution of fishing activities in these fisheries is monitored using VMS, to ensure fishing activities remain outside sensitive habitats, as well as monitor the intensity of fishing activities in any one location.

Pilbara Inshore (Shelf)

<td>Marine, Sand/Mud Sponge, Seagrass, Reef</td>
<td>MODERATE (fishing), LOW (non-fishing)</td>
</tr>
</tbody>
</table>

The Pilbara Inshore Ecosystem comprises the broad North West Shelf area off the Pilbara coast and includes all waters seaward of the 20 m depth contour to depths of 250 m and includes a number of mid-shelf islands. The Pilbara Inshore Ecosystem includes sections of three IMCRA Bioregions: Pilbara Offshore, Eighty Mile beach and the southern part of the North West Shelf.

Ecosystem

Given the large areas closed to both trawling and to all commercial fishing, there is only a low risk that the level of fishing in this region is changing the regional-level community structure to an unacceptable level. Assessments of the community structure and trophic level of all commercially caught fish species in the region over the past 30 years found no evidence that there have been any

systematic changes. Therefore, there is no indication that the fish faunas have been impacted by the development of the scalefish fisheries to the extent that ecosystem function in the Pilbara Inshore Ecosystem has been affected (Hall and Wise 2011). The majority of catch from each fishery is comprised of the main target species, and catches of these species have remained stable throughout the history of each fishery. None of the main target species are known to be involved in any strong ecological interactions and their removal at current rates is unlikely to seriously or irreversibly alter community structure. The total catch of the largest demersal scalefish fishery, the Pilbara Fish Trawl Fishery Interim Managed Fishery has declined from annual average catch levels of close to 2500 t during 1995 – 2004, to an average of 1200 t per annum since 2008. This is considered to be due to effort restrictions that were imposed by the trawl industry in 2008 and the Department in 2009. It is unlikely that total removals would significantly disrupt the trophic dynamics of the region, as most species in the catch are generalist carnivores that consume a wide range of fish and invertebrates from demersal habitats. Additionally, there are other species of medium-sized carnivores in the Pilbara Inshore Ecosystem that are not caught in significant quantities by the Fishery and contribute to the total biomass of carnivores in the region. These non-target species play a similar trophic role to targeted species and are likely to compensate for the effect of removals by the fishery.

**Habitat**

Although fish trawling occurs in these areas, trawl activities are tightly constrained. The large area permanently closed to trawling and the relatively small area where trawling actually occurs indicates that the habitat in this region is appropriately managed. Trawl activities are considered to have the highest habitat impacts of the methods used within the region; however, the majority of trawling takes place of sand/mud bottom habitats, and there are a variety of measures in place to manage any impacts. A number of measures are in place to manage the impact of the Pilbara Fish Trawl Fishery Interim Managed Fishery on benthic habitats including gear restrictions, effort restrictions and spatial closures. All trawl nets are required to have rubber discs (max. diameter of 350 mm) attached to the ground rope which allow the net to fish slightly off the bottom and ride over obstructions, such as sponges. The maximum diameter of the rubber discs is aimed at restricting the movement of trawlers to areas of soft/flat seabed. There are also spatial constraints throughout the Fishery, including depth restrictions and closed areas. Trawling is only permitted in waters deeper than 50 m, which provides an inshore refuge area for targeted benthos from which recruitment onto the trawl area is possible. Large areas over the 0 – 200 m depth range within the fishing boundaries are also closed to trawling. The location of fishing activities are reported in daily logbooks and monitored with VMS. Fishing levels are such that the fished area of the Pilbara Demersal Scalefish Fishery (PDSF; trawl, trap and line sectors) between depths of 30 and 120 m should remain at or below 60 % of the total fishing area. With the current spatial restrictions on fishing activities (see above), only 46 % of the PDSF area and less than 5 % of the NorthWest Shelf is accessible to trawl vessels. Plots of trawl activity from VMS data indicate that the actual area trawled is significantly less than this. The most likely potential impacts to the habitat in this area are from oil and gas infrastructure development and operation.

### Offshore Oceanic Shoals

The Offshore Oceanic Shoals Ecosystem (OSE) includes the waters beyond the shelf break, with depths greater than 250 m. This ecosystem includes one IMCRA v.4 Bioregion, the Offshore Oceanic Shoals.

**Ecosystem**

There are a number of specific oil and gas related offshore developments that are proposed in this region, particularly around Scott Reef. At the overall ecosystem level, however, there is only a low risk that the ecosystem will be altered measurably. The majority of fishing activities is focused around islands, reefs and shoals, which are known to be areas of localized productivity. The area around Ashmore Reef, Cartier Island and Scott and Seringapatam Reefs is an important area for traditional fishers from Indonesia and can be accessed by the fishers through a Memorandum of Understanding (MoU), which was agreed between the Australian and Indonesian Governments in 1974. In 1983, Ashmore Reef and Cartier Island were declared nature reserves, and by 1989, the collection of trepang was prohibited following overfishing from Indonesian fishers. Currently, traditional fishing activities are spatially restricted and fishers are permitted to obtain a maximum finfish catch for immediate consumption and one days sailing only. The Northern Demersal Scalefish Fishery and the Mackerel Managed Fishery also operate in the area around these reefs and islands, including at Woodbine and Johnson Banks. The cumulative ecological impacts from these fishing activities are minimal, as there is no significant commercial effort in the Offshore Oceanic Shoals Ecosystem.

**Habitats**

The main threat to benthic habitats in this ecosystem is from oil and gas development at Scott Reef. A small amount of line fishing occurs around these offshore shoals and reefs but is likely to have a negligible impact on the benthic habitat.

### Northern Pelagic

The Northern Pelagic Ecosystem includes the pelagic waters and suite of species found within the North Coast Bioregion ‘above’ the inshore demersal and offshore demersal suites.

**Ecosystem**

Historical fisheries in the region include the Northern Shark Fishery (NSF) and Mackerel Managed Fishery (MMF) which operate in the pelagic component of the North Coast Bioregion and are based on based on gillnet/ longline and trolling gear types respectively. The NSF has, however, not

**STATUS REPORTS OF THE FISHERIES AND AQUATIC RESOURCES OF WESTERN AUSTRALIA 2014/15**

169
operated since 2009. The main species targeted and caught by the MMF are fast swimming, pelagic carnivores. In 2012, 332 t of mackerel and other pelagic species were retained by the fishery with Spanish mackerel comprising over 99% of the total catch. Spanish mackerel are generalist carnivores and consume a wide range of fish and invertebrate species from both pelagic and demersal habitats. Therefore, the impact of any reduction in abundance of mackerel species would be spread across many prey species. Additionally, mackerel are just one of many medium-sized carnivore species in the northern waters of WA, and any reduction in mackerel abundance would have little impact on the total biomass of carnivores in each region.

**Habitats**
The fishing gear used in the Northern Pelagic Ecosystem does not contact the sea bed during fishing operations. Within the Mackerel Managed Fishery (MMF), fishing trips may last for several days, during which time the vessels anchor overnight in sheltered locations. The main impact on the benthic habitat in the fishery is likely to be from this anchoring activity, however, anchors are typically set over naturally dynamic sandy habitats and any impacts from anchoring are wide spread throughout the fishing area.

**Captured Species**

**Finfish**
The principal fisheries in the North Coast Bioregion focus on tropical finfish, particularly the high-value emperors, snappers and cods. These species are taken by the Pilbara Demersal Scalefish Fishery (trawl, trap and line sectors) and the Northern Demersal Scalefish Fishery (tarp and line). The typical catch is in the order of 3000 t annually at an estimated annual value of around $12 million, making these fisheries the most valuable finfish sector in the state. A number of other finfish fisheries operate in the Bioregion, including near-shore beach seining and gillnetting for barramundi and threadfin salmon (the Kimberley Gillnet and Barramundi Managed Fishery) and surface trolling for Spanish mackerel (the Mackerel Managed Fishery). The Department manages commercial, charter, recreational and indigenous fishing in the State coastal waters (generally 3 nm). By way of the Offshore Constitutional Settlement 1995 (OCS) agreement between the State and Commonwealth Governments, control is also given to WA for most fisheries which operate out to 200 nm from the coast (except for trawling where WA’s jurisdiction is limited to the 200 m isobath). Indicator species which reflect the characteristics of the broader exploited stocks are monitored in order to assess ecological risk to the ranges of species targeted.

**Estuarine/ Nearshore (0-20m depth)**

<table>

</tbody>
</table>

The Kimberley Gillnet and Barramundi Managed Fishery (KGBF) is the only commercial fishery operating in the nearshore and estuarine zones of the North Coast Bioregion. It encompasses the taking of any fish by means of gillnet in inshore waters and the taking of barramundi (*Lates calcarifer*) by any means. The primary target species are barramundi and threadfin salmon. The KGBF is managed through input controls in the form of: limited entry; seasonal closures; area closures; and gear restrictions (e.g. net length and mesh size). Access to the Fishery is limited to five licence holders since two in Roebuck Bay bought out. There is no indication that the fish faunas have been impacted by the development of the scalefish fisheries to the extent that ecosystem function in the ecosystem has been affected (Hall and Wise 2011). Stocks of barramundi and threadfin salmon are considered to be at acceptable levels.

### Inshore (shelf) Demersal (20-250 m depth)

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

There are four State-managed commercial fisheries in the Inshore Demersal region, which use multiple methods to target demersal fish stocks. These fisheries include: The Pilbara Fish Trawl (Interim) Managed Fishery (PFTIMF); The Pilbara Trap Managed Fishery (PTMF); The Pilbara Line Fishery (PLF); and The Northern Demersal Scalefish Managed Fishery (NDSF).

These fisheries all target the tropical demersal scalefish suite in the Pilbara and Kimberley Inshore Ecosystem and are collectively referred to as the Pilbara Demersal Scalefish Fisheries (PDSF) and Kimberley Demersal Scalefish Fisheries (KDSF). The trawl fisheries land the largest component of the catch, comprising more than 50 scalefish species. The current status of demersal finfish stocks captured by the Pilbara trawl fishery requires a review. A research survey is underway to assist in determining if the recent low catch rates are due to changes to trawl gear or to localized depletion.

**Pelagic**

<table>
<thead>
<tr>
<th>Captured Species</th>
<th>Aquatic zone</th>
<th>Ecological Risk</th>
</tr>
</thead>
<tbody>
<tr>
<td>Finfish</td>
<td>Pelagic</td>
<td>MODERATE</td>
</tr>
</tbody>
</table>

The Spanish Mackerel stock in this region targeted by the Mackerel Managed Fishery is at acceptable levels, and there are few other pelagic fish that are impacted.

**Invertebrates**

A significant commercial invertebrate fishery in this Bioregion, is the Pearl Oyster Managed Fishery, which is based on the collection of pearl oysters (*Pinctada maxima*) for use in the aquaculture production of pearls. These are collected from the fishing grounds primarily off Eighty Mile Beach, with smaller catches being taken around the Lacepede Islands (north of Broome).

The North Coast Bioregion also has a number of small, limited-entry trawl fisheries for prawns, producing around
700 t annually and valued at around $10 million. These fisheries include the Onslow, Nickol Bay, Broome and Kimberley Prawn Managed Fisheries (collectively referred to as the North Coast Prawn Managed Fisheries). Two small trap-based crab fisheries also exist in the Bioregion, targeting blue swimmer crabs in the Pilbara (the Pilbara Developing Crab Fishery) and mud crabs in the Kimberley (the Kimberley Developing Mud Crab Fishery). Sea cucumbers (also known and bêche-de-mer or trepang) are collected by hand by divers and waders throughout the Kimberley region as part of the Bêche-de-Mer Fishery. Catches are mainly comprised of two species, sandfish (Holothuria scabra) and redfish (Actinopyga echinata). The Trochus Fishery is a small fishery based on the collection of a single target species, Tectus niloticus from King Sound and the Buccaneer Archipelago. This fishery is operated by the Bardi Jawi and Mayala Aboriginal Communities, who have been collecting trochus in this area since the 1960s.

### Estuarine/Nearshore

<table>
<thead>

<tr>
<td>Bêche-de-Mer</td>
<td>Nearshore</td>
<td>LOW</td>
</tr>
</tbody>
</table>

There is a small amount of fishing for mud crabs and blue swimmer crabs in some estuarine and inshore areas and its ecological risk is considered to be low.

The North Coast Trochus Fishery in King Sound is an indigenous fishery targeting the commercially important gastropod shell Tectus niloticus, commonly known as trochus. It is a hand collection fishery open to nominated fishers from the community. No fishing took place in 2012.

The pearl oyster fishery only targets a very small section of the pearl oyster stock both spatially and within the available size range. Recent catches have been well below the quota levels due to low market demand but are beginning to increase again.

Bêche-de-mer, also known as ‘sea cucumbers’ or trepang, are commercially harvested echinoderms (sea slugs) processed and sold for medicinal purposes in Asia. The majority of the effort has been expended in the Kimberley region, although there have been several years with substantial effort directed into the Pilbara region.

### Inshore (shelf)

<table>
<thead>
<tr>
<th>Captured Species</th>

<th>Ecological Risk</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prawns</td>
<td>Inshore (shelf)</td>
<td>MODERATE</td>
</tr>
</tbody>
</table>

There are a number of separate prawn stocks and fisheries within this Bioregion and each has limited entry, seasonal and area closures. Annual recruitment to these stocks is variable, which combined with the higher costs of operating in this region, has resulted in fishing effort being much lower in recent years.

### Listed species

A number of endangered, threatened and protected (ETP) species can be found within the North Coast Bioregion, including cetaceans, dugongs, marine turtles, sea snakes, elasmobranchs, seahorses and pipefish, crocodiles and seabirds and migratory shorebirds. These species are protected by various international agreements and national and state legislation. International agreements include:

- Convention on the Conservation of Migratory Species of Wild Animals 1979 (Bonn Convention);
- The Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES);
- The Agreement between the Government of Australia and the Government of Japan for the Protection of Migratory Birds in Danger of Extinction and their Environment 1974 (JAMBA);
- The Agreement between the Government of Australia and the Government of the People’s Republic of China for the Protection of Migratory Birds and their Environment 1986 (CAMBA);
- The Agreement between the Government of Australia and the Government of the Republic of Korea on the Protection of Migratory Birds 2007 (ROKAMBA);
- Any other international agreement, or instrument made under other international agreements approved by the environment minister including the EBPC Act 1999.

Primary pieces of national and Western Australian legislation include the Commonwealth Environment Protection and Biodiversity Act 1999 (EPBC Act), the Western Australian Wildlife Conservation Act 1950 (WC Act), and the Fish Resources Management Act 1994 (FRMA).

The only fisheries in the region that have reported any interactions with ETP species are the two trawl fisheries, the Onslow Prawn Managed Fishery (OPMF) and the Nikol Bay Prawn Managed Fishery (NPBMF) and the Kimberley Gillnet Barramundi Fishery (KGBF). ETP interactions with the trawl fisheries are few, due to fishing arrangements, such as the use of bycatch reduction devices and the separation of trawling activities from most ETP species’ primary habitat. Similarly, Fishers in the KGBF actively avoid capturing ETP species; however, a small amount of interactions have been reported with saltwater crocodiles and sawfish.

### Fish

<table>

<td>Syngnathids and Solenotomids</td>
<td>LOW</td>
</tr>
<tr>
<td>Other Fish</td>
<td>LOW</td>
</tr>
</tbody>
</table>

1 Note that being on a listed species list does not automatically indicate that a species is either threatened or endangered.

2 Further information on the CMS, JAMBA, CAMBA and ROKAMBA is provided at www.environment.gov.au/biodiversity/migratory/index.html
The sawfish (Pristidae), speartooth shark (Glyphis glyphis) or the northern river shark (Glyphis garricki) are captured in small numbers by net fishing and trawlers in some areas of the Kimberley region. The area of these fisheries in which sawfish are vulnerable to capture is small relative to the total range of each species, suggesting limited impacts on each population. However, elasmobranchs grow and reproduce slowly, and even low levels of fishing mortality may be unsustainable.

Sea horses and pipefish are occasionally captured in trawl nets and fish/crab traps. The areas of each fishery in which syngnathids and solenostomids are vulnerable to capture is small relative to the total distribution of the species, which includes waters inshore of the fishery and fishery closed areas, as well as structured habitats where trawling does not occur.

Recent video observations indicate that the potato cod is present in high numbers at discrete locations within the Kimberley region where the NDSF operates. Potato cod (Epinephelus tukula), a totally protected species, rarely enter fish traps due to their large size and girth limiting their capacity to pass through the entrance funnel into fish traps.

Sea snakes and occasionally turtles are encountered in trawl catches. Both of these species are typically returned to the sea alive. Grids are now compulsory on trawl nets, which has largely eliminated the capture of any turtle or other large animal.

Crocodiles are occasionally captured in nearshore/ freshwater fisheries’ nets and most often are released alive.

Dolphins are captured by the Pilbara trawl fishery, but dolphin excluder devices have reduced this incidence to acceptable levels, with further refinements in net design currently being trialled. The Pilbara fish trawl fishery recently secured a three year WTO with further conditions around dolphin and sawfish interactions and monitoring.

Anecdotal information from Lake Argyle fishers suggests that interactions with birds and crocodiles are very low.

Additionally, the fishery is closed from 1 November to 31 December each year, during a high-use period for protected migratory birds.

### Introduced Pests Status Report

#### Regional Monitoring and Research Update

The introduction and spread of marine pests in WA waters poses a serious threat to native biodiversity and can have widespread effects on both our economy and health. There are two key vectors for marine pest translocation: ballast water and hull fouling. The Marine Biosecurity Research Group continues to implement a series of biosecurity related projects in the North Coast Bioregion which include detection strategies and vessel risk analyses.

Early detection of IMPs is vital if any attempt at eradication or other management strategies is to be successful. Thus the Marine Biosecurity Research Group undertakes regular and comprehensive marine pest monitoring at the ports of Dampier and Port Hedland. This monitoring incorporates a three tiered approach. First the undertaking of a nationally approved design, second a more targeted monitoring program and third a program using permanently in-situ sampling equipment (Early Warning System). The national system monitoring adheres to the Australian Marine Pest Monitoring Guidelines and is endorsed by the Commonwealth, and occurs every second year. The targeted monitoring is a smaller more focussed survey designed to target select high risk sites in each port and established by the Marine Biosecurity Research and Monitoring Group to fill in the gap between the national system surveys (i.e. the alternate years). The national system monitoring of Dampier port was completed in early 2015, with monitoring in Port Hedland Port scheduled for later in 2015. The next round of complementary monitoring for these ports is scheduled for 2016. The Early Warning System program, which uses in-situ sampling arrays to aid in the early detection of marine pests in both ports, is run by the Marine Biosecurity Research Group, with financial and in-kind assistance from the Pilbara Ports Authorities and stakeholders, and the private ports of Cape Preston and Cape Lambert. This program provides a cost-effective mechanism for the potential early detection of marine pests in these waters. Through this combined surveillance the introduced marine pest species that have been detected since initiation of these projects in this bioregion are reported in Introduced Pests Table 1.

From a biosecurity perspective the introduction of a marine pest to any region is based on multiple factors that can be grouped into two themes; the likelihood of inoculation and the likelihood of infection and establishment. Inoculation likelihood assumes that the greater the number of vessel visits...
from a source with introduced marine pests (IMP) the greater the risk of IMPs being brought into the recipient port i.e. a positive linear relationship. The number of commercial vessels entering the North Coast Bioregion has significantly increased (~1600%) over the past 12 years (2002 to 2014). As a result the Marine Biosecurity Research Group is analysing the change in numbers of commercial vessels as well as their visit and type profiles to better inform management processes of the domestic and international risks to the Bioregion.

The group is also examining the risk recreational vessels pose with respect to introducing, harbouring and translocating IMPs around the State. This project involves surveying marina-based vessel owners about their vessel management practices and their vessel use profiles. The research outputs are designed to be applicable to biosecurity management across the state.

For further details on the above projects see the Appendix section entitled “Activities of the Marine Biosecurity Research Group during 2014/15”.

Fishery Description

The four prawn fisheries that operate in the North Coast Bioregion include the Onslow (OPMF), Nickol Bay (NBPMF), Broome (BPMF) and Kimberley (KPMF) Prawn Managed Fisheries. These are all otter trawl fisheries and extend from the north eastern boundary of the Exmouth Gulf Prawn Fishery to 126° 58’ east longitude (Cape Londonderry – boundary of the Northern Prawn Fishery).

The OPMF and NBPMF operate along the western part of the North-West Shelf. The OPMF targets western king prawns (*Penaeus latisulcatus*), brown tiger prawns (*Penaeus esculentus*), endeavour prawns (*Metapenaeus spp.*) whereas the NBPMF primarily targets banana prawns (*Penaeus merguiensis*).

The BPMF operates in a designated trawl zone off Broome and targets western king prawns (*Penaeus latisulcatus*) and coral prawns (a combined category of small penaeid species).

The KPMF operates off the north of the state between Koolan Island and Cape Londonderry. It predominantly targets banana prawns (*Penaeus merguiensis*) but also catches tiger prawns (*Penaeus esculentus*), endeavour prawns (*Metapenaeus endeavouri*) and western king prawns (*Penaeus latisulcatus*).

Commonwealth Government Environment Protection and Biodiversity Conservation Act 1999 (Export Exemption)

Consultation process
The Department undertakes consultation directly with licensees on operational issues. Industry Annual Management Meetings are convened by the Western Australian Fishing Industry Council (WAFIC), which is also responsible for statutory management plan consultation under a Service Level Agreement with the Department. For statutory management plan processes, the Director General consults with licensees.

Boundaries
The boundaries of the OPMF are ‘all the Western Australian waters between the Exmouth Prawn Fishery and the Nickol Bay prawn fishery east of 114°39.9’ on the landward side of the 200 m depth isobath’. The fishery is divided into three parts with associated Size Management Fish Grounds (SMFGs) and nursery areas as follows: Area 1, incorporating the Ashburton SMFG; Area 2, incorporating the Mangrove Island and Weld Island SMFGs and Coolgra Point Nursery; and Area 3, incorporating the Fortescue SMFG (Northern Prawn Figure 1).

The boundaries of the NBPMF are ‘all the waters of the Indian Ocean and Nickol Bay between 116°45’ east longitude and 120° east longitude on the landward side of the 200 m isobath’. The NPBMF incorporates the Nickol Bay, Extended Nickol Bay, Depuch and De Grey SMFG’s (Northern Prawn Figure 2).

The boundaries of the BPMF are ‘all Western Australian waters of the Indian Ocean lying east of 120° east longitude and west of 123°45’ east longitude on the landward side of the 200 m isobath’. The actual trawl area is contained within a delineated small area north west of Broome as shown in Northern Prawn Figure 3.

The boundaries of the KPMF are ‘all Western Australian waters of the Indian Ocean lying east of 123°45’ east longitude and west of 126°58’ east longitude’. It abuts the western boundary of the Commonwealth Northern Prawn Fishery (NPF). The KPMF has four inshore closures and two SMFGs in place (Northern Prawn Figure 4).

Management arrangements
Management of all the north coast prawn fisheries is based on input controls including limited entry, seasonal and area closures, and gear controls including bycatch reduction devices. Fish Escape Devices are mandatory in all trawl nets. The Department’s Vessel Monitoring System (VMS) monitors the activities of all boats.

OPMF: The management arrangements in the OPMF involve using a standardised net headrope allocation whereby each Managed Fishery Licence (MFL) has an equal allocation of net headrope length in each Area. However, there are different net sizes permitted between Areas. Trawl net headrope amalgamation between MFLs has been permitted in the OPMF consistent with other trawl fisheries. The fleet is composed of trawlers up to 23 metres in length. Additionally, the fishery is exempt from the 375 boat unit rule.

Different licence classes apply to the OPMF, allowing boats to trawl in specific zones. These classes are listed below, with figures in brackets indicating number of licensed boats:
- Class A: Areas 1, 2 and 3 (4 MFLs)
- Class B: Areas 2 and 3 (3 MFLs)
- Class C: Area 2 (11 MFLs, that are also Exmouth Gulf Prawn MFLs)
- Class D: Area 3 (12 MFLs that are also Nickol Bay prawn MFLs)

The 2014 season officially opened on 21 April and closed on 8 October with subsidiary openings and closings of SMFG’s. The specific SMFG openings were as follows:
- Areas 1, 2, 3: 21 April – 8 October
- Fortescue SMFG: 01 June – 8 October
- Ashburton SMFG: 21 May – 12 July
- Weld Island SMFG: 21 May – 31 August
- Mangrove Island SMFG: 21 May – 8 October

NBPMF: The management arrangements in the NBPMF provide for authorised boats to tow standard otter trawl nets not exceeding 29.27 metres (16 fathoms) each boat. The 2014 season opened on 24 March and closed on 31 October with subsidiary openings and closings of SMFG’s. Nickol Bay and Depuch SMFGs were open for daylight fishing only (0600 hrs and 1800 hrs) between 21 May and 4 June. The specific SMFG openings were as follows:
- Nickol Bay: 21 May – 2 October (Day fishing only 21 May – 4 June)
- Extended Nickol Bay SMFG: 21 May – 31 October
- Depuch SMFG: 21 May – 2 October (Day fishing only 21 May – 4 June)
- De Grey SMFG: 21 May – 2 October

BPMF: The BPMF management arrangements provide for the use of standard otter trawl nets not exceeding 73.16 metres (40 fathoms) in either twin or single gear configuration. The Fishery opened on 1 June and officially closed on 8 October, providing for 128 fishing nights.

KPMF: The KPMF Management Plan permits the use of two otter trawl nets where the total headrope length does not exceed 58.5 metres (32 fathoms). There are 121 boats licensed to fish in the KPMF, 45 of these also held an NPF licence.

Seasonal dates for the KPMF are generally aligned with those of the adjacent NPF. This strategy aims to prevent large shifts of fishing effort into the KPMF. There are permanent inshore closures and a total allowable effort cap system in place that restricts the number of fishing days to a total of 1500 days, with 600 and 900 boat days allocated to the first
and second part of the season respectively. The fishery opened on 1 April with a mid-season closure commencing on 27 May. The fishery re-opened on 1 August, with a final season closure on 30 November. A slight change of the southern boundary area to the Admiralty Gulf closure designed was trialled for the 2014 season to increase access to prawn abundances. This trial will be in place for the 2015 and 2016 season.

A comprehensive Ecologically Sustainable Development assessment of these fisheries has been undertaken to identify any potential sustainability risks requiring direct management action. The only issue identified through this process related to the breeding stock levels of target species (e.g. banana, tiger and king prawns). Boxed text in this status report provides the annual assessment of performance for this issue. The Department of the Environment (DotE) completed the reassessment of the NBPMF, OPMF, KPMF and BPMF trawl fisheries and export approval has been granted for ten years (re-assessment in 2025) for all fisheries under the one approval.

Research summary

Research programs are focused to underpin the sustainable management of these small fisheries involving stock monitoring and assessment utilising information from daily logbooks and processor unloads.

In the OPMF a field-based consultative process is normally undertaken whereby industry and the Department’s Research Division decide on the extent of an area to be fished within the areas that are officially opened, and to limit the fishing of small size prawns. For 2014 limited commercial fishing was undertaken and uncertainty of fishing viability in Area 1 the most productive area in this fishery still remains as in 2013. Area 3 was fished by three boats from the NBPMF, which has access to that part of the Onslow fishery.

For the NBPMF and KPMF rainfall records are also used to update the rainfall-catch relationship for banana prawns. A preliminary harvest strategy with control rules has been developed for these fisheries.

Landings

**OPMF:** The total recorded landings in the OPMF were <0.5 t comprising of brown tiger prawns and banana prawns (Northern Prawn Figure 5).

**NBPMF:** The total recorded landings of major penaeids for the 2014 season reported by the Nickol Bay fishers was 211 t, comprising: 171.1 t of banana prawns from the Nickol Bay fishery, and 14.8 t from Onslow, Area 3, (providing a total of 185.9 t), 24.9 t of tiger prawns, and negligible amounts of western king and endeavour prawns. These are the highest catches of banana and brown tiger prawns since 2006. (Northern Prawn Figure 6).

Byproduct has been reported since 2000. For 2014, byproduct comprised; 4.9 t of blue swimmer crabs (*Portunus armatus*), and <1 t of bugs (*Thenus orientalis*), cuttlefish and squid species. Since 2000 the total recorded byproduct landings have been very low except for 2004 when high squid and bugs landings were recorded. Generally bugs are sought after because of their high relative value but since 2007 recorded annual landings have been less than 1 t.

**BPMF:** No landings were recorded as no boats fished in 2014. Boats briefly sampled the area on two occasions, but the catch rate was considered to be low and no commercial fishing was therefore undertaken (Northern Prawn Figure 7). The cost to fish, particularly high fuel prices was a major factor in fishers deciding not to fish.

**KPMF:** The total recorded landings in the KPMF were 287 t, comprising 269 t of banana prawns, 8 t of brown tiger prawns and 10 t of endeavour prawns (Northern Prawn Figure 8). Banana prawns landings were within the target catch range and within the catch prediction range of 230 to 350 t calculated using the relationship between summer rainfall and annual landings. Since 1980, banana prawn landings have ranged between 150 and 450 t. The endeavour prawn annual landings were within the target catch range and the tiger prawns annual landings were slightly below the target catch range. Fishing occurred in both fishing periods and the second part of the season produced catches comparable with historical monthly catches. Negligible quantities of byproduct were reported.

Recreational component:

Nil

Fishing effort/access level

**OPMF:** Area 1 boats are authorised to use two trawl nets each having a maximum headrope length of 10.98 metres (6 fathoms), a maximum of total headrope of 87.84 metres (48 fathoms). These boats operate under an exemption to fish with larger size nets. In Areas 2 and 3 a maximum headrope length of 29.27 metres (16 fathoms) is permitted in either twin or quad gear configuration. There was limited fishing by one boat during the 2014 season in Area 1 only. All other catch recorded for the fishery was taken from Area 3 by Nickol Bay boats and these catches are reported in the Nickol Bay section.

**NBPMF:** Each licence has an equal allocation of headrope length and the maximum total headrope length for the entire fleet is 409.78 metres (224 fathoms). Seven boats fished during the 2014 season for a total of 272 boat days. Most of the fishing effort was applied in May, June and July where 7 boats fished in May and June and 4 boats in July, after that only two boats fished in August, one boat in September and October. This is the highest effort reflecting the higher abundance of banana prawns since 2006.

**BPMF:** Each of the five licences in this fishery has an equal allocation of net headrope of 73.16 metres (40 fathoms) and the maximum total headrope length for the entire fleet is 365.8 metres (200 fathoms). No effort was expended in the BPMF in 2014 (Northern Prawn Figure 7).
KPMF: Although a total of 121 managed fishery licences have access to the KPMF, only nine boats operated in the fishery during 2014. The number of boats is low compared to the years prior to 2008 (Figure 6). The total number of days recorded by VMS when boats were physically within the fishery boundaries were 570 days and well below the allocated fishing days (1500) (Table 2). The data from daily logbooks indicate that 437 boat activity days were recorded in the fishery which includes searching. However of these 437 boat days there were only 389 days when boats actually recorded fishing effort and catch (Northern Prawn Figure 8).

Stock Assessment

Assessment complete: Yes
Assessment level and method: Level 1 - Catch
(Rainfall-catch relationship for NBPMF and KPMF for banana prawns, depletion analysis for BPMF - when appropriate)

Breeding stock levels: Adequate
Projected catch next season (2015):
NBPMF: 61 t banana prawns
KPMF: 260 t banana prawns

For the prawn stocks in the North coast region their short life cycle, high fecundity and dispersed nature prevent fishing from depleting breeding biomass to unacceptable levels. Historical catch levels from periods where it is known that recruitment was not affected by fishing effort have been used as the basis for calculating target catch ranges. These catch ranges are used as an indicator of breeding stock adequacy.

The recent series of low annual landings of prawns is still a feature in many of these northern fisheries and are in part due to low effort caused by the current economic conditions including, high fuel and equipment prices and low market prices and variable market conditions. Catches of banana prawns are highly variable and related to the amount of rainfall recorded in the region with consecutive high rainfall years providing the optimal conditions for banana prawn recruitment.

OPMF: There was limited commercial fishing undertaken in 2014. The total landings of prawns were extremely low. There has been disruption and disturbance to some productive Area 1 fishing grounds. Approval for trawl fishing activity must be sought from the Regional Authority because of pipeline on the seabed from the offshore gas platforms and general boat movement in the area making fishing operations difficult. Since there was little catch and also effectively no effort on the brown tiger prawn stock in this part of the fishery, adequate breeding stock would remain. This also applies for the western king prawn stock.

NBPMF: The recorded landings of banana prawns in 2014 from Nickol Bay were slightly above the predicted catch range (114 to 171 t) but within the target range (40 – 220 t). The brown tiger prawn catch was within the target range (2 – 40 t) and the western king prawn landings were extremely low and below the target range for this species. The catch projection for banana prawns in Nickol Bay is based on the annual catch between December and March (Northern Prawn Figure 9). The total rainfall between December 2014 and March 2015 (at Roebourne) was 74.2 mm and the predicted catch for 2015 is 61 t with a range of 48–73 t of banana prawns. However, there has been late rainfall in the region and this could provide increased abundance of banana prawns but is recognized as being outside the normal environmental conditions range that has historically been used.

BPMF: No landings were recorded as no boats fished the BPMF in 2014.

KPMF: Throughout the history of the fishery, the stock of banana prawns in the Kimberley has been assessed using the annual catch (tonnes). This is consistent with a DoF Level 1 assessment. The catch is compared against specified reference levels for catch, i.e. a target catch range (200 – 450 t) and we now also propose a catch limit reference point of 100 tonnes, provided the effort also remains within the historical range. The target historical catch range spans the observed catches in most years, apart from four years where the catch was below the target range. The 2014 landings are within the target catch range for banana prawns. Several additional indicators of stock abundance based on raw catch per unit effort (CPUE) have been explored and may have potential for use in future assessments, once a longer time series is available of daily logbook records. Also a preliminary biomass dynamics model was developed as part of the MSC pre-assessment. The relationship between annual catches and rainfall is used to broadly predict the amount of banana prawn catch likely to be available to fishers during the fishing season however, the relationship is relatively weak. The relationship is based on the rainfall in Kalumburu and Derby in January and February (which was 475 mm in 2015). The predicted catch of banana prawns in 2015 is 260 t, with a range of 210 to 315 t.

The main performance measures for the OPMF, NBPMF and KPMF relate to maintenance of breeding stocks for each of the major target prawn species.

In 2014 the breeding stock indicators in the OPMF (catches within specified ranges, as set out in the ‘Fishery governance’ section) could not be assessed as negligible fishing and hence landings occurred which would have provided maximum protection to the entire stock from fishing.

The main performance measures for the Nickol Bay fishery relate to maintenance of breeding stocks for each of the major target prawn species. In 2014 the breeding stock indicators (catches within specified ranges i.e. 40 to 220 t of banana prawns, as set out in the ‘Fishery Governance’ section) for banana prawns were met. There is no trend of an increased prevalence of low catch years in the last two decades. In 2014, the annual catch was within the target catch range, despite low effort, indicating adequate overall stock (and breeding stock) abundance. Brown tiger prawn landings were within the target range (2-40 t) whilst western king prawn landings were extremely low and below the acceptable range (2-70 t). Whether these low western king prawn catches are due to low stock levels, very limited targeting on this species or due to environmental factors is
Non-Retained Species

Bycatch species impact: Low

Bycatch from the northern prawn fisheries is typical of tropical trawl fisheries (i.e. from 2:1 up to about 5:1 relative to the target species), but the effort levels and spatial coverage are too low to impact bycatch species’ populations. The introduction of fish escape devices (FEDs) within all the nets towed by each vessel has reduced this risk even further. The NBPMF and KPMF fishery operates predominantly by specifically targeting schools of banana prawns. This targeting of schools of banana prawns results in relatively low effort and minimal bycatch compared with other trawl fisheries. The impact on bycatch in the OPMF was negligible due to very low effort. No fishing was undertaken in the BPMF. All trawl nets have grids to exclude large fish and most listed species.

Listed species interaction:

OPMF, BPMF: Nil

NBPMF, KPMF: Negligible

The northern prawn fisheries have previously caught the occasional turtle and sea snakes and the overall low effort level and targeted coverage suggest that such interactions would not have been significant. Bycatch reduction devices (‘grids’) and FEDs are now fully implemented minimising the capture of large animals including turtles.

NBPMF: In 2014, 12 turtles (8 green, 1 hawksbill and 3 unidentified) were recorded as captured and released back to the sea alive. Twenty two sea snakes were reported as caught. Twelve were released alive and 10 reported as dead. Fifteen sawfish (status unknown) were reported as captured.

KPMF: Nineteen sea snakes were reported as captured. Fifteen were returned to the sea alive whereas 4 were reported dead. Six sawfish were reported as captured, and returned to the sea alive.

Ecosystem Effects

Food chain effects: Low

For all the northern prawn fisheries and in particular the OPMF with limited fishing and no fishing in the BPMF the limited spatial coverage of the Onslow fishery and low levels of effort and catch, it is unlikely to have any significant ecological consequences. In addition for the NBPMF and the KPMF, the highly variable nature of banana prawn recruitment, positively related to cyclonic rainfall, any food chain impacts from fishing are likely to be minimal.

Habitat effects:

OPMF, BPMF: Negligible

NBPMF, KPMF: Low

In 2014 the area fished in the three northern fisheries where fishing took place ranged from 2.1% in the Kimberley fishery to <1% in the Nickol Bay and Onslow fisheries whereas the Broome fishery was not fished, are within the overall area of these fisheries (Northern Prawn Figures 1-4). The fisheries are generally restricted to clean sand and mud bottoms, where trawling has minimal long-term physical impact. Because there was limited fishing activity in the OPMF the habitat effects was changed from low to negligible.

Social Effects

Estimated employment in these fisheries for 2014 was 40 to 60 including skippers and other crew with additional people involved in local processing.

Economic Effects

Estimated annual value (to fishers) for 2014:

OPMF/NBPMF/BPMF/KPMF:

Level 3 - $5 - 10 million ($5.3 million)

Fishery Governance

OPMF Target catch range: 60 – 180 tonnes

Current fishing level: Negligible

Under normal effort levels and previous environmental conditions, the target ranges of prawn catches, based on the catches of the 1990s, are as follows:

King prawns 10 – 55 t
Tiger prawns 10 – 120 t
Endeavour prawns 5 – 20 t
Banana prawns 2 – 90 t

NBPMF Target catch range: 90 – 300 tonnes

Current fishing level: Acceptable

Banana prawns 40 – 220 t
King prawns 20 – 70 t
Tiger prawns 2 – 40 t

BPMF Target catch range: 55 – 260 tonnes

Current fishing level: Nil

Under current effort levels and previous environmental conditions, the target ranges of prawn catches are as follows:

King prawns 35 – 170 t
Coral prawns 20 – 90 t

For king prawns the target range is based on the catches of the 1990s, while for coral prawns it is based on the seven-year range (1996 – 2002) since catches were first recorded.
KPMF Target catch range: 240 – 500 tonnes

Current fishing level: Acceptable

Under current effort levels and previous environmental conditions, the target ranges of prawn catches, based on the catches of the 1990s, are as follows:

- **Banana prawns**: 200 – 450 t
- **Tiger prawns**: 15 – 60 t
- **Endeavour prawns**: 7 – 80 t

The overall target range for all species combined is different from the aggregate of the individual species ranges shown above. This is because the environmental circumstances that benefit banana prawns generally result in decreased catches of the other species. Effort is now considered a factor when reviewing target catch ranges in these northern fisheries.

**New management initiatives (2015):**

The KPMF is scheduled for a management review in 2015. As part of the review the Department will be liaising with licensees in the KPMF regarding the options to implement management arrangements aimed at increasing the viability of the KPMF operators.

**External Factors**

The resource industry developments in the OPMF during 2014 continue with uncertainty about the access to prawn abundance in traditionally high catching fish grounds and overall viability of operations.

Banana prawns are rainfall dependent and can be highly variable annually in the KPMF, NBPMF and for the OPMF where banana prawns may be in some years be taken predominantly off the mouth of the Ashburton River. Due to high costs of fishing and low prawn prices, some boats in these fisheries are choosing not to fish in years of relatively low banana prawn catches. In the BPMF one factor influencing catches is the timing of the season which is set by the mid-season closure for the Northern Prawn Fishery, and, since the permitted fishing area is small, in some years the timing of prawn recruitment and the prawn migration patterns may not result in significant abundances in the permitted fishing area. The success of this fishery also depends on how the limited fishing season coincides with the king prawn recruitment and catchability, which is strongly influenced by the lunar period.

The marine heatwave event in 2010/11 and continued higher than average water temperatures in northern WA waters may be having a negative effect of abundance of western king prawns which could also be contributing to the very low landings of this species in all of these northern fisheries.

**Fishery Description**

**Commercial**

The Kimberley Gillnet and Barramundi Managed Fishery (KGBF) operates in the nearshore and estuarine zones of the North Coast Bioregion from the WA/NT border (129°E) to the top end of Eighty Mile Beach, south of Broome (19°S). It encompasses the taking of any fish by means of gillnet in inshore waters and the taking of barramundi (*Lates calcarifer*) by any means.

Along with barramundi, the other main species taken by the fishery are king threadfin (*Polydactylus macrochir*) and blue threadfin (*Eleutheronema tetracyclum*). The focal areas of operation for the fishery are the river systems and tidal creek systems of the Cambridge Gulf, the Ria coast of the northern Kimberley and King Sound. In late 2013, Roebuck Bay and the northern end of Eighty Mile Beach to 19°S were closed to commercial fishing (Kimberley Gillnet Figure 1). This ‘Broome coast’ area historically provided the majority of threadfin catches in the fishery.

**Recreational**

Recreational fishing activities are concentrated around key population centres, with a seasonal peak in activity during the dry season (winter months).

**Governing legislation/fishing authority**

**Commercial**

*Kimberley Gillnet and Barramundi Managed Fishery Management Plan 1989*
Kimberley Gillnet and Barramundi Managed Fishery Licence.

Recreational
Fish Resources Management Act 1994; Fish Resources Management Regulations 1995 and other subsidiary legislation.

Consultation processes
Commercial
The Department undertakes consultation directly with licensees on operational issues. Industry Annual Management Meetings are now convened by the Western Australian Fishing Industry Council (WAFFC), who are also responsible for statutory management plan consultation under a Service Level Agreement with the Department.

Recreational
Consultation processes are now facilitated by Recfishwest under a Service Level Agreement although the Department undertakes direct consultation with the community on specific issues.

Boundaries
Commercial
The waters of the KGBF are defined as ‘all Western Australian waters north of 19° south latitude and west of 129° east longitude and within three nautical miles of the high water mark of the mainland of Western Australia and the waters of King Sound south of 16°21.47’ south latitude’ (Kimberley Gillnet Figure 1).

Recreational
The North Coast Bioregion, which encompasses the Pilbara and Kimberley regions, extends from the Ashburton River south of Onslow to the WA/NT border (all land and water north of 21°46’S latitude and east of 114°50°E longitude).

Management arrangements
Commercial
The KGBF is managed primarily through input controls in the form of limited entry, seasonal and spatial area closures and gear restrictions. Access to the KGBF is limited to five licences, following the buyout of the two licences from the Broome coast (Roebuck Bay) in 2013.

There is a closed season in which fishing is prohibited in the KGBF. In the southern KGBF (west of Cunningham Point, 123°08.23’E longitude) the closure extends from 1 December to 31 January the following year, while in the northern section of the KGBF (east of Cunningham Point) the closure extends from 1 November to 31 January the following year (see Kimberley Gillnet Figure 1). There are also limits on the length of net and mesh sizes to be used in the fishery.

There are now only three principal fishing areas within the KGBF: Cambridge Gulf (including Ord River), Kimberley coast (six small river systems) and King Sound. Following the buyout of the two licences from the Broome coast (Roebuck Bay), this area is now closed to commercial fishing.

In addition to the Broome coast (Roebuck Bay) closure, there are commercial fishing area closures around major town sites and recreationally important fishing locations.

Recreational
Fish species in the North Coast Bioregion are assigned bag and size limits according to their ecological suite and risk to sustainability. The bag and size limits are species-specific (e.g. barramundi) or species group specific (e.g. mullet) to ensure that stock levels are maintained. These bag and size limits have been revised and new simpler rules that apply across most Bioregions were introduced in 2013. These new rules include the following: barramundi (individual daily bag limit and possession limit of 2 fish, minimum legal length (MLL) of 550 mm and a maximum size limit of 800 mm); black jewfish (individual daily bag limit of 2 fish, MLL 700 mm); king threadfin (individual daily bag limit of 2 fish, MLL 450 mm); other threadfin species (individual daily bag limit of 4 fish) and tripletail (individual daily bag limit of 2 fish, MLL 300 mm).

Recreational set and haul netting is prohibited in all waters of the North Coast Bioregion with the exception of haul netting in the waters of the Dampier Archipelago (between Cape Preston and Cape Lambert) with the following restrictions: haul nets must not exceed 30 metres in length; mullet are the only species to be retained and all other species must be returned to the water.

Research summary
Monthly catch and effort data from the commercial fishery are used to assess the status of barramundi and threadfin populations targeted by this fishery. This status report is compiled annually and provided to industry and fisheries’ management officers.

The biological characteristics required for fisheries management for both threadfin species have been studied (Pember et al. 2005). In addition, the stock structure of both threadfin species was defined by Welch et al. (2010). The results from both of these studies will be considered in future monitoring and assessment programs of threadfin. The bycatch of elasmobranchs in the KGBF and the previous Pilbara Coast fishing area was examined during 2002 and 2003 (McAuley et al. 2005). Estimates of recreational boat- and shore-based catches were assessed in 1999/2000 (Williamson et al. 2006) and an integrated survey of boat-based recreational fishing in WA was conducted during

---

boat-based fishers that fished only in freshwater out of scope of the 2011/12 survey.

The reported charter vessel catches for the North Coast Bioregion in 2014 were estimated to be approximately 3.7 t of barramundi and approximately 2.7 t of threadfin.

As such, there is an estimated annual harvest of 12.1 t of barramundi (recreational + charter) reported in the North Coast Bioregion. In addition, there is an estimated annual harvest of 9.7 t of all threadfin (recreational + charter) reported in the North Coast Bioregion.

Noting that these data underestimate the total recreational catch (as explained above), the recreational catch of barramundi can be estimated at around 25% of the total (commercial and recreational) catch in these areas in 2012. The recreational catch of threadfin can be estimated at around 15% of the total (commercial and recreational) catch in these areas in 2012.

**Fishing effort/access level**

**Commercial**

The effort reported in the fishery is block days. The effort determination used in the fishery is currently being reviewed but as fishing practices vary across the industry and are not uniform, it is difficult to utilise a more refined determination of effort expenditure for this fishery. For example, some fishers actively fish their nets for a few hours while others leave their nets in the water for up to 24 hours. Furthermore, reporting practices are inconsistent across time. It is anticipated that effective effort in the fishery, once validated, will reflect the total length of net set and the time that net is set in the water. During 2014, the total effort across the fishery was 433 block days, a decrease on the 2013 effort of 184 block days. The reported charter vessel catches for the North Coast Bioregion in 2014 were estimated to be approximately 3.7 t of barramundi and approximately 2.7 t of threadfin.

**Recreational**

A summary of the key findings of the 2011/12 integrated survey of boat-based recreational fishing in regards to barramundi, blue and king threadfin by Ryan et al. (2013) are provided below.

- Recreational catches of barramundi by RFBL holders occurred in the North Coast Bioregion. The majority of the boat-based recreational catch of barramundi was released or discarded (72%). The majority of the catch was taken in estuary habitats (64%), but also in freshwater (21%) and nearshore areas (16%). Barramundi were harvested throughout the year, with higher catches observed in winter (38%), spring (29%) and autumn (20%). All the barramundi catch was taken by line-fishing.

- All recreational catches of blue and king threadfin by RFBL holders aged five years or older occurred in the North Coast Bioregion. Similar proportions of the boat-based recreational catch of blue threadfin were retained (54%) and released (46%). Catches were taken

---

predominantly from nearshore habitat (86%), but also estuarine habitats (14%). Blue threadfin were harvested throughout the year, with higher catches observed in winter (71%) compared with spring (6%), summer (3%) and autumn (20%). All catches were taken by line fishing.

- The majority of the boat-based recreational catch of king threadfin was retained (66%). Catches were taken from estuary (51%) and nearshore (49%) habitats. King threadfin were harvested throughout the year, with higher catches observed in autumn (45%) and spring (42%) compared with winter (4%) and summer (9%). All catches were taken by line fishing.

**Stock Assessment**

**Assessment complete:**
- Barramundi: Yes
- Threadfin: Yes

**Assessment level and method:** Level 2 - Catch Rate

**Breeding stock levels:**
- Barramundi: Adequate
- Threadfin: Adequate

The level of catch of barramundi decreased in 2014 from 2013 levels but was similar to the 10 year (2004-2013) average. Whilst the catch of barramundi in 2014 was slightly lower than in 2013, the catch of threadfin was substantially lower than that reported in 2013 and the 10-year average. This decrease can be attributed to the closure of the Broome coast (Roebuck Bay) area, which had historically provided the majority (~80%) of threadfin catches in the fishery.

The commercial catch rates for barramundi in the KGBF increased in 2014 (102.1 kg/block day) to the highest level reported in the period since 1990 (Kimberley Gillnet Figure 3). This continues an increasing trend in the barramundi catch rate for the past three years. The catch rate for threadfin in 2014 (54.1 kg/block day) across the fishery was much lower than that reported in 2013 (90.88 kg/block day) and below the long-term (1990-2013) average (84.7 kg/block day). This decrease in threadfin catch rate can be attributed to the Broome coast closure.

There is the potential for localised depletion risks to barramundi and threadfin populations given their fine scale spatial stock structure.

**Non-Retained Species**

**Bycatch species impact:** Low

The fishery operates at a relatively low intensity over a wide area of the Kimberley region, specifically targeting barramundi and threadfin. The fishing gear uses large mesh sizes, and hence does not generate a significant bycatch of species important to other sectors, but does take some sharks and rays. Where practicable, sharks and rays are released alive. However, there is some mortality of sharks and rays associated with gillnet capture. Because of the low spatial density of fishing effort relative to the widespread distribution of these species and the size-selectivity of the permitted mesh sizes, these impacts are unlikely to be significant to the stocks involved.

**Listed species interaction:** Low

The fishing gear used for this fishery (gillnets) is known to result in the bycatch of protected saltwater crocodiles (*Crocodylus porosus*) and sawfish (*Family Pristidae*). These species are generally released alive or avoided as far as is practicable. Because of the low effort levels and the low spatial intensity of fishing effort, these impacts are unlikely to pose a significant threat to the sustainability of the stocks of these species. Commercial fishers are required to report any interactions with endangered, threatened and protected (ETP) species. In 2014, interactions were reported with two crocodiles and 17 sawfish, with all but one sawfish released alive.

Catches of the spearothshark (*Glyphis glyphis*) or the northern river shark (*Glyphis garricki*), which are listed under the Environment Protection and Biodiversity Conservation Act 1999 as critically endangered and endangered, respectively, are rare in the KGBF. However, as these species look similar to other whaler shark species, they may be captured but misidentified. Given the fishery’s overall low effort levels, particularly inside the freshwater drainages in which these species are most likely to occur, and the closure to net fishing in the Fitzroy River and all its creeks and tributaries south of 17° 27’ south latitude (a known area for the northern river shark (Morgan et al. 2004)), the fishing operations of the KGBF are unlikely to pose a significant threat to the sustainability of the stocks of these species. Any increase in effort levels inside freshwater drainages will need to be monitored.

**Ecosystem Effects**

**Food chain effects:** Low

This fishery poses a minimal risk on the nearshore and estuarine ecosystem of the Kimberley region.

**Habitat effects:** Low

The fishing gear has minimal impact on the habitat. The area and habitat fished is subject to extreme tidal currents and associated effects and is typically mud flat areas.

**Social Effects**

**Commercial**

During 2014, four of the five licensed vessels in the KGBF actively fished, with an average crew level of approximately 2.5 people, with an estimate of at least 10 people directly employed in the fishery. There was additional employment through local processors and distribution networks. The fishery provides fresh fish for the local communities and the tourism industry throughout the Kimberley region.

---

Recreational
A significant number of recreational and charter anglers also fished across the region.

Economic Effects
Estimated annual value (to fishers) for 2014:

Level 1 - < $1 Million

The value of the North Coast Nearshore and Estuarine Fishery was reported using the 6 categories defined in Fletcher et al. (2010) that are used to assess the relative economic (based on gross value product, GVP) and social amenity value associated with each ecological asset. These values are based on GVP figures derived from the 2013-14 financial year.

Historically, the KGBF principally targeted the high-value species, barramundi and threadfin. With the closure of Broome coast (Roebuck Bay), the future catches from the KGBF will primarily consist of barramundi (as observed in 2014), since the majority of the threadfin catches were historically derived from this Broome coast area. The fishery’s score value in 2014 was estimated to be 1 (i.e. Risk level – Negligible; Economic value – <$1 million).

However, the social amenity classification for the KGBF is determined as ‘Important’ (this fishery is an important asset locally and/or the use or existence of the asset is important to the broader community).

Fishery Governance
Target commercial catch range:

Barramundi: 33-44 tonnes

Current Fishing (or Effort) Level: Acceptable

The target commercial catch range is calculated based on catch information from 1990 – 1999, a long-term period during which the fishery was stable and levels of exploitation were considered to have been sustainable. Note that the target catch range for barramundi has recently been revised to be consistent with the reference points and control rules adopted for other fisheries. The current approach specifies this range as the values within the minimum and maximum catches observed during the reference period. The revised target commercial catch range (33 – 44 t) is similar to that previously used (32 – 45 t). As such, the threshold values for the target commercial catch range have been calculated as being within the range of 33 – 44 t, with a limit reference range of 23-54 t.

The level of barramundi catch was within the target catch range from 2000-2002, 2005-2006 and 2012. The barramundi catch in 2003, 2004, 2008-2010 and 2013 was above the target range, mainly as a result of increased effort levels in different areas of the fishery. The increase in catch in 2013, however, occurred despite a decrease in fishing effort in the Broome and Kimberley Coast areas of the fishery. This resulted in high catch rates which may suggest a recent increase in stock biomass for barramundi. In only two years (2007 and 2011) was the barramundi catch below the target catch range. This reduced catch was associated with reduced effort levels in the fishery in those years. The barramundi catch in 2014 was 44.2 t, and at the upper end of the target catch range. In 2013, two licences were removed from the Broome area of the fishery (Roebuck Bay closure). This sector of the fishery is now recreational and indigenous fishing only. This effort removal is likely to produce reduced levels of catch in future years. The current fishing level is considered to be acceptable although the reference points will need to be reviewed given the removal of the two licensees and the associated reduced effort in the fishery.

A review of the fishery is planned and will include reviews and updates of the status of the barramundi stock, the current fishing and effort levels and the target catch range for barramundi.

New management initiatives (2015/16)

The KGBF management plan was amended in June 2012 to modernise the fishery management arrangements. The next management review of the fishery is due after the 2015 /16 financial year.

External Factors

The barramundi stocks utilising the Kimberley river systems as nursery areas are expected to be reasonably resilient to fishing pressure. However, the impact of increasing exploitation from the charter and tourism sectors, as well as population growth associated with the gas and mining development sectors on barramundi stocks needs to be monitored.

An additional related factor to the impact of increasing recreational fishing pressure that requires monitoring is the post-release mortality of barramundi. The 2011/12 boat-based recreational survey identified that the majority (72%) of the catch of barramundi in WA was released or discarded (Ryan et al. 2013), however a Northern Territory study observed that the post-release survival rate of barramundi in freshwater systems was high (~90%) (de Lestang et al. 2004).

Furthermore, the smaller, isolated stocks along the arid Pilbara coastline are likely to experience highly variable recruitment due to environmental fluctuations (e.g. the amount of rainfall). These stocks will be subject to increased exploitation pressure from recreational fishers (driven by regional population growth resulting from gas and mining developments), and specific management arrangements may be needed in the future.

In addition, the introduction of new marine parks (State and Federal) across the Kimberley region has the potential to concentrate fishing effort from multiple sectors into those areas that are easily accessible, further increasing risks of local depletion of barramundi and threadfin stocks.

The KGBF underwent MSC pre-assessment in 2014. Outcomes from the pre-assessment are currently under review.

Fishery Description

There are a number of commercial and recreational fisheries that operate in the northern bioregion which target, to varying degrees, the following tropical, demersal fish species (in order of gross tonnage); goldband snapper (*Pristipomoides multidens*), red emperor (*Lutjanus sebae*), crimson snapper (*Lutjanus erythropterus*), bluespotted emperor (*Lethrinus punctulatus*), saddletail snapper (*Lutjanus malabaricus*), brownstripe snapper (*Lutjanus vitia*), Rankin cod (*Epinephelus multinoitatus*), rosy threadfin bream (*Nemipterus furcosus*) and spangled emperor (*Lethrinus nebulosus*). Each of these fisheries is outlined below.

Commercial

Pilbara

The Pilbara Demersal Scalefish Fisheries include the Pilbara Fish Trawl (Interim) Managed Fishery, the Pilbara Trap Managed Fishery and the Pilbara Line Fishery, which collectively use a combination of vessels, effort allocations (time), gear limits, plus spatial zones (including extensive trawl closures) as management measures. The Trawl Fishery lands the largest component of the catch of demersal finfish in the Pilbara (and North Coast Bioregion) comprising more than 50 scalefish species. In comparison, the trap fishery retains a subset of about 45 to 50 scalefish species, and while the Line Fishery catch comprises a similar number it also includes some deeper offshore species, e.g. ruby snapper (*Etelis carbunculus*) and eightbar grouper (*Hyporthodus octofasciatus*).

Kimberley

The Northern Demersal Scalefish Managed Fishery (NDSF) operates off the northwest coast of Western Australia in the waters east of 120° E longitude. The permitted means of operation within the fishery include handline, dropline and fish traps, but since 2002 it has essentially been a trap based fishery which uses gear time access and spatial zones as the primary management measures. The main species landed by this fishery are red emperor and goldband snapper.

Recreational

Recreational fishing activities on these species are mostly line based fishing from boats which are concentrated in inshore areas around key population centres, with a peak in activity during the dry season (winter months, April/May to September/October).

Consultation processes

Commercial
The Department undertakes consultation directly with licensees on operational issues. Industry Annual General Meetings are convened by the West Australian Fishing Industry Council (WAFIC), who are also responsible for statutory management plan consultation under a Service Level Agreement with the Department.

Recreational
Consultation processes are now facilitated by Recfishwest under a Service Level Agreement although the Department undertakes direct consultation with the community on specific issues.

Boundaries

Commercial
Pilbara
The Pilbara Fish Trawl Interim Managed Fishery is situated in the Pilbara region in the northwest of Australia. It occupies the waters north of latitude 21°35'S and between longitudes 114°9'36'E and 120°E. The Fishery is seaward of the 50 m isobath and landward of the 200 m isobath (North Coast Figure 1). The Fishery consists of two zones; Zone 1 in the south west of the Fishery (which is closed to trawling) and Zone 2 in the North, which consists of six management areas. Areas 1 to 6 each cover 1,300; 1,800; 880; 1,500; 2,300 and 7,200 square nautical miles, respectively. The total area available for trawling in Zone 2 is 14,980 square nautical miles; however, only 6,900 square nautical miles are currently open (i.e. ~46% of Zone 2 is currently open to trawling). This represents less than 5% of the total shelf area available in the North Coast Bioregion. The exact latitudes and longitudes delineating the areas are listed in the Pilbara Fish Trawl Fishery (Interim) Management Plan 1997. The Pilbara Trap Managed Fishery (North Coast Figure 1) lies north of latitude 21°44'S and between longitudes 114°9.6'E and 120°00'E on the landward side of a boundary approximating the 200 m isobath and seaward of a line generally following the 30 m isobath. The exact latitudes and longitudes delineating the fishery are listed in the Pilbara Trap Management Plan 1992.

The Pilbara Line fishing boat licensees are permitted to operate anywhere within "Pilbara waters". This means all waters bounded by a line commencing at the intersection of 21°56’S latitude and the high water mark on the western side of the North West Cape on the mainland of Western Australia; thence west along the parallel to the intersection of 21°56’S latitude and the boundary of the Australian Fishing Zone and north to longitude 120°E. The exact latitudes and longitudes delineating the Fishery are listed in the Prohibition on Fishing by Line from Fishing Boats (Pilbara Waters) Order 2006.

Kimberley
The waters of the Northern Demersal Scalefish Fishery are defined as all Western Australian waters off the north coast of Western Australia east of longitude 120°E. These waters extend out to the edge of the Australian Fishing Zone (200 nautical miles) (North Coast Figure 1). The fishery is further divided into two fishing areas; an inshore sector (Area 1) and an offshore sector (Area 2; see North Coast Figure 1). The Northern Demersal Scalefish Managed Fishery Management Plan 2000 was amended in 2013 to formalise the previous voluntary industry agreement which further divides the offshore sector (Area 2) into 3 zones; A, B and C. Zone B comprises the area with most of the historical fishing activity. Zone A is an inshore developmental area and Zone C is an offshore deep slope developmental area representing waters deeper than 200 m. The inshore waters in the vicinity of Broome are closed to commercial fishing. This closure was put in place to reduce the potential for conflict between commercial fishers and recreational, charter and customary fishers (North Coast Figure 1).

Recreational
Recreational fishing in the North Coast Bioregion encompasses all waters in both the Pilbara and Kimberley regions, extending from the Ashburton River south of Onslow to the WA/NT border with the exception of some areas within Marine Parks.

Management arrangements

Commercial
Pilbara
The Pilbara Fish Trawl Interim Managed Fishery is managed through a combination of area closures, gear restrictions, and the use of input controls in the form of individual transferable effort allocations monitored by a satellite-based vessel monitoring system (VMS). This Interim Management Plan was implemented in 1998, with effort levels determined to achieve the best yield from the Fishery while keeping exploitation rates of the indicator species at sustainable levels. Currently, the Interim Management Plan has a cessation date of 30 June 2016.

A large amount of the area within the boundaries of the Trawl Fishery is closed to trawling. Much of this has been closed since the implementation of the Interim Management Plan (1998) including Zone 1 of the Fishery and Area 3 of Zone 2 of the Trawl Fishery. In addition, Area 6 of Zone 2 has been closed since the commencement of the Interim Management
Plan except for two periods of research trawling in 1998 and 1999. The area inshore of the 50 m depth isobath is also closed to trawling. Areas 1, 2, 4 and 5 are open to trawl fishing all year round, with separate effort allocations (in hours) in each of the Areas, as outlined in the Interim Management Plan. The open areas of the Trawl Fishery are trawled with varying intensity due to differing effort allocation, substrate composition and economic considerations (e.g. distance from ports). There are 11 permits for the Fishery, with the combined effort allocations being consolidated over time onto 3 full time vessels. The Trap Fishery is also managed primarily by the use of input controls in the form of individual transferable effort allocations monitored with a satellite-based VMS. There has also been a closure to trapping in Area 3 since 1998. The authority to fish in the Trap Fishery is limited by reference to a specified number of trap days expressed in terms of units of entitlement. The capacity is currently limited to 5,456 trap days. However, the Management Plan allows the Director General to alter the value of these units. There are 6 licences in the Fishery, with the allocation consolidated onto 3 vessels. The Line Fishery is managed under the Prohibition on Fishing by Line from Fishing Boats (Pilbara Waters) Order 2006. Nine Fishing Boat Licences are exempted from this prohibition for any nominated 5-month block period within the year. There has also been a closure to line fishing for demersal scalefish in Area 3 since 1998.

Comprehensive Ecological Sustainable Development (ESD) assessments were submitted to the Commonwealth Government’s Department of the Environment (DotE), in 2004 for both the Pilbara Trap and Trawl Fisheries to allow product to be exported. These ESD assessments determined that performance should be assessed annually for breeding stock levels, listed species interactions and habitat effects. As a result, the Pilbara Trap Fishery was declared an approved Wildlife Trade Operation in November 2004 for a period of three years. This was not renewed after December 2007 as the fishery was not exporting. The Pilbara Fish Trawl Interim Managed Fishery has been re-accredited as an approved Wildlife Trade Operation until May 2017.

Kimberley
The Northern Demersal Scalefish Fishery is managed primarily through input controls in the form of an annual fishing effort capacity, with supplementary gear controls and area closures. The annual fishing effort capacity limits the amount of effort available in the fishery to achieve the notional target total allowable catch. The annual effort capacity is set by the Director General based on the available research advice in consultation with licensees. This effort capacity is then allocated among licence holders through units of entitlement on Managed Fishery Licences, for use in Zones A, B and C in Area 2 of the Fishery. In 2014, the annual effort capacity was 616 fishing days for Zone A, 985.6 fishing days in Zone B and 1,100 fishing days for Zone C. However, the Director General may prohibit further fishing in Zone C if the total amount of fishing in Zone C reaches 550 fishing days. The notional target TAC for Zone B is a recommended level of catch for the entire demersal species suite and is derived from the estimated sustainable catch of the key target species (determined through stock assessments) and their historical proportions in the catch. The areas that encompass Zone A and Zone C are likely to have a lower sustainable catch compared with Zone B, and thus exploratory TACs are set for Zone A and Zone C. These will need to be revised as effort and catches in these zones increase.

Access to the offshore sector (Area 2) of the NDSF is limited to 11 licences under an individually transferable effort (ITE) system. This allows the effort quota to be operated by a lesser number of vessels. For example, during 2014, 8 vessels (fishing in zones A, B and C) collectively held and operated the effort individually assigned to the 11 licences. Each trap must have an internal volume equal to or less than 2.25 m³. While there is no restriction on the number of traps that can be fished per vessel, each licensee is allocated an annual effort quota in ‘standard fishing days’ based on the use of 20 traps (or 5 lines) per day. The number of allowable fishing days declines, if the number of traps (or lines) being fished increases beyond this level. The number of days and traps fished, as recorded by the vessel monitoring system, is converted to standard fishing days. A comprehensive environmental risk assessment of this fishery has determined that performance should be reported against measures relating to breeding stocks of the two indicator species, red emperor and goldband snapper, and the cod/grouper complex (a suite of more than 10 species), as reflected by their catch levels.

Recreational
The recreational fishery for demersal fish in the North Coast Bioregion is managed in a manner to other Bioregions across the State through the use of input controls (e.g. size limits) and output controls (e.g. limits on the numbers of fish that can be taken by individuals and boats – these are assigned based on a number of risk categories). Since 2 March 2010, all persons fishing from a powered boat anywhere in the state have been required to hold a Recreational Fishing from Boat Licence or fish in the company of a licence holder. The Recreational Fishing from Boat Licence provides a statewide database of recreational boat fishers that can be utilised for survey purposes.

Demersal fish, particularly the iconic species such as coral trout and red emperor, are considered prime recreational target species. As such, resource-sharing issues will be a consideration in future management arrangements across this Bioregion.

Research summary

Pilbara
Monitoring and assessment of the Pilbara Trawl, Trap and Line Fisheries includes the collection of spatial data on effort and catch of 11 major target species and the total retained catch from statutory logbooks, VMS data, and weighed catches from unload data. Assessment of the status of the suite of retained demersal scalefish is based on the performance of indicator species (primarily including red emperor, Rankin cod, bluespotted emperor, brownsnipe snapper, goldband snapper and ruby snapper) using various assessment methods constituting a weight-of-evidence approach. These methods include trend analysis of trawl
catch rates using two measures of effort (time spent trawling as reported in statutory logbooks and time spent in each management area derived from VMS pollings) for five indicator species and the total catch in each of the trawl-managed areas. In addition, ages are determined from otolith sections for selected indicator species in each trawl-managed area and the Trap Fishery, and for ruby snapper from the Line Fishery.

Estimates of fishing mortality are derived from age structures and compared to internationally recognised biological reference points (see Stock Assessment section). Approximately every 4-5 years the spawning biomass of two indicator species, red emperor and Rankin cod, are assessed using the age-composition and catch rate data synthesised into an integrated age-structured model.

In 2010, a fishery independent research survey was conducted which involved an ecological assessment of the demersal fish assemblages and habitat characteristics across trap, trawl and closed (Area 3) management areas.

An intense six month independent observer program designed to monitor bycatch and interactions with endangered, threatened and protected species was completed in 2012 in order to meet a specific set of conditions from DotE within the WTO for the Fishery. The outcomes of this observer program are reported in Fisheries Research Report 244.

**Kimberley**

Assessment of the status of the demersal fish stocks in Zone B of the NDSF is determined annually using catch and catch rates of the major species or species groups, and every ca. 5 years using an age-based stock assessment model where applicable to assess the status of two indicator species, red emperor and goldband snapper, based on age-composition data collected in previous years. The next assessment (2015) will incorporate age composition data collected during 2012 from two surveys conducted on board industry vessels. Age composition data were collected from both fixed and random sites within the fished areas of Zone B of Area 2 of the NDSF. Ongoing monitoring of this fishery is being undertaken using both catch and effort logbook and VMS data.

The catch from the NDSF also includes components from Zone A of the fishery. The level of catch from Zone A will be monitored closely in the future as this area of the fishery has been receiving more effort in recent years.

The catch from the NDSF also includes at times some species from the waters of Zone C in depths greater than 200 m. The resources of this Zone are unlikely to be substantial, and given the lower productivity of these longer-lived, deeper-slope reef fish, the sustainable catch from this zone is likely to be significantly lower than for Zone B.

### Retained Species

**Commercial landings (season 2014):**

- **Pilbara Fish Trawl**: 1,105 tonnes
- **Pilbara Fish Trap**: 268 tonnes
- **Pilbara Line**: 40 tonnes
- **Kimberley (NDSF)**: 1,111 tonnes

The commercial catches of key species and species groups from across the North Coast Bioregion and their relative contribution to catches within the Pilbara and Kimberley sectors in 2014 are summarised in North Coast Table 9. The relative contribution of the Kimberley sector has been increasing as the catch from the Pilbara sector has been stable.

**Pilbara**

The total catch of demersal scalefish taken by the trawl fishery has declined from an annual average catch of close to 2,500 t during the period 1995 – 2004 to an average of 1,157 t per annum since 2008 (North Coast Tables 1 and 2). These total annual catches have been below the target catch range (2,000 to 2,800 t) for eight consecutive years, with 1,105 t landed in 2014 (North Coast Table 2). These lower annual catches are considered to be a response to the effort reductions imposed on the trawl fishery since 2008.

The catches of the major target species landed by the trawl fishery were generally similar or slightly higher in 2014 than the previous year, i.e. crimson snapper 152 t (132 t in 2013), bluespotted emperor 93 t (98 t in 2013), rosy threadfin bream 93 t (76 t in 2013), goldband snapper 86 t (80 t in 2013), brownstripe snapper 71 t (66 t in 2013), saddletail snapper 64 t (53 t in 2013), red emperor 48 t (54 t in 2013), spangled emperor 11 t (11 t in 2013) and Rankin cod 7 t (11 t in 2013). The total retained byproduct was 16 t (8 t in 2013) and included bugs, cuttlefish, and squid (North Coast Table 2).

The total annual catch taken by the Pilbara trap fishery has remained relatively consistent 2004-2013 averaging 440 t per year (North Coast Tables 1 and 2). In 2014, the total catch of 268 t was below the target catch range of 400-500 t, but was associated with reduced effort in the fishery (North Coast Table 2 and 3). The major species taken by the trap fishery in 2014 were red emperor 54 t (49 t in 2013), bluespotted emperor 49 t (41 t in 2013), Rankin cod 37 t (43 t in 2013), goldband snapper 28 t (61 t in 2013), and crimson snapper 22 t (32 t in 2013).

The total annual catch of scalefish taken by the line fishery is historically much lower than that taken annually by the trawl and trap fisheries (North Coast Tables 1 and 2). In 2014, the total annual catch for the line fishery was 40 t, which was lower than that taken in 2012 (85 t) and slightly lower than the target catch range of 50-115 t (North Coast Table 2). This lower catch in 2014 was associated with reduced effort in the fishery (North Coast Table 2 and 3). In recent years (since ~2006), the line fishery catches have been dominated by ruby snapper and goldband snapper, typically accounting for more than 40% of the total annual catch. In 2014, the ruby snapper catch was 11 t (12 t in 2013) and the goldband snapper catch was 15 t (31 t in 2013) (North Coast Table 1). This fishery and the Commonwealth’s North West Slope Trawl Fishery are likely to be targeting the same stock (management unit) of ruby snapper, so catches from both commercial fisheries need to be considered in any future assessment or development of a harvest strategy.

**Kimberley**

The NDSF catches over the past six years have all been in excess of 1,000 t, and represent the highest recorded catches since the inception of the fishery in 1998. This continued in 2014 with total landings of 1,111 t. The Zone B component of the 2014 catch (960 t) is the highest reported. In contrast, the total catch of Zone A in 2014 (145 t) was much reduced.
and is the lowest reported since 2009 (135t). The highest reported catch in Zone A of the fishery was 291 t in 2013 (North Coast Tables 6 and 7).

The NDSF principally targets red emperor and goldband snapper, with a number of species of snappers (Lutjanidae), cods (Epinephelidae) and emperors (Lethrinidae) comprising the majority of the remainder of the catch (North Coast Table 6). The species composition of the landed catch in 2014 is similar to that reported in 2013, with goldband snapper dominating the landed catch. The landed catch of goldband snapper in 2014 (499 t) was similar to that reported in 2013 (493 t). Catch levels of goldband snapper have remained high (> 450 t) since the peak catch of 523 t reported in 2010. The last five years represent the highest reported landings of this species, continuing an overall trend of increasing catches since 2005. The total catch of red emperor in 2014 was 132 t, which is similar to the red emperor catch levels reported over the past four years (2010-2013). The cods/groupers catch in 2014 (168 t) was less than that reported in 2013 (195 t), although the catch in B Zone (135 t) was the highest reported for that sector. It continues a trend of higher catch levels for the cods/groupers since 2002. Rankin cod dominates the composition of the cod/grouper catch complex. The catch of Rankin cod decreased from 62 t in 2013 to 51 t in 2014 (North Coast Table 7).

The catches reported above represent those derived from all zones of the NDSF. It is noteworthy that the catch of cods/groupers in Zone A has largely driven the overall higher catches of this complex since 2010. The decrease in the overall cods/groupers catch in 2014 is partly a result of the reduction in catch and effort in Zone A. The catches from Zone B also consist of a large number of species which are not well represented in the Zone B catch; these include bluespot emperor (Lethrinus puncitulatus) and crimson snapper (Lutjanus erythropterus). In 2014, this mix of Zone A species (‘other fish’) constituted 61t (42%) of the overall catch from Zone A.

The catch rate of red emperor in Zone B in 2014 was slightly above those recorded during the period 2009-13. However, recent catch rates are lower than those reported for this species from 2005-08 (North Coast Figure 4). Total landings were also significantly higher during this period. The catch rates for goldband snapper in Zone B increased slightly, and remained within the high range reported since 2008. These consistently high catch rates (2009–2014) have been maintained following the sharp increase in catch rates for goldband snapper in the period from 2006-2008 (North Coast Figure 5). The catch rate for the cod/grouper complex in Zone B in 2014 also increased slightly, exceeding the highest catch rate previously reported in 2012. This continues a period of generally increasing catch rates for this species complex since 2005, with particularly high levels of catch rate since 2010 (North Coast Figure 6).

The 2014 catch of red emperor, goldband snapper and the cods/groupers all within acceptable levels as defined in the Export exemption for this fishery (see ‘Fishery Governance’ section), with no species or species group exceeding the threshold level (20% increase in average catch of the previous 4 years).

### Recreational catch estimate (season 2014):

<table>

### North Coast Bioregion

The most recent state-wide survey of boat-based recreational fishing in WA was conducted during 2013/14 (Ryan et al. 2015). Estimates from this survey comparable to the state-wide survey of boat-based recreational fishing conducted in 2011/12.

A total of 153 finfish species were taken in the North Coast Bioregion (both Pilbara and Kimberley; Ryan et al. 2015). The most common were: stripey snapper (14%), grass emperor (12%), spangled emperor (9%), barcheek coral trout (4%), and barramundi, blackspot tuskfish, blackspotted rockcod, blue tuskfish, golden trevally and Spanish mackerel (3% each). These 10 species accounted for 57% of the total catch (by numbers). There is little overlap with the main species landed by recreational fishers and those landed by the commercial fisheries covered in this report.

An estimated annual harvest of 48 – 64 t was reported for the top 10 demersal species in the North Coast Bioregion in 2013/14 (Ryan et al. 2015). In terms of estimated harvest, the estimated catch of the top 10 demersal species were grass emperor (12.1 t), barcheek coral trout (7.6 t), red emperor (7.4 t), Rankin cod (6.5 t), spangled emperor (6.3 t), blackspot tuskfish (5.6 t), stripey snapper (3.4 t), crimson snapper (2.7 t), mangrove jack (2.6 t) and golden snapper (2.0 t).

The estimated recreational boat-based catch of the top 10 demersal species in the North Coast Bioregion has decreased from the 76 t (s.e.~12 t) reported in 2011/12 (Ryan et al. 2015). The estimated recreational catches were steady between 2011/12 and 2013/14 for: barcheek coral trout, blackspot tuskfish, grass emperor, Rankin cod and red emperor. However, the estimated recreational catches of spangled emperor decreased between 2011/12 and 2013/14 from 15 t (95% confidence intervals from 11–19) to 6 t (95% confidence intervals from 4–9).

Even though the catch estimate of the top 10 demersal species is an underestimate of the total recreational catch, the total demersal recreational catch can be estimated to be at least ~2% of the combined (commercial and recreational) demersal scalefish catch in the North Coast Bioregion in 2014. In addition, the red emperor recreational catch can be estimated to be ~3% of the combined (commercial and recreational) red emperor catch in the North Coast Bioregion in 2014 and the Rankin cod recreational catch can be estimated to be ~6% of the combined (commercial and recreational) Rankin cod catch in the North Coast Bioregion in 2014.

### Pilbara

While there is a major recreational fishery in the Pilbara and the charter sector is an increasing user of the resource, the inshore closures to the commercial sector provide a degree of spatial separation between the user groups. The recreational and charter sectors do not catch significant quantities of most species.
species targeted by the commercial Pilbara demersal scalefish fisheries.

The reported charter vessel catch of demersal scalefish in the waters of the Pilbara demersal fisheries in 2014 was estimated to be 18.7 t (spangled emperor – 5.6 t; Rankin cod – 4.4 t; goldband snapper – 1.8 t; crimson snapper – 1.8 t; saddletail snapper – 1.7 t; chinamanfish – 2.1 t; ruby snapper – 0.4 t). The Pilbara charter vessel catch is estimated to be ca. 1.3% of the Pilbara commercial catch of demersal fish.

Kimberley

Historically, there has been little recreational or charter boat fishing effort directed towards the demersal fishes in Area 2 of the NDSF, the species that are targeted by commercial fishers. However, this is now changing with charter vessels moving into the inshore demersal waters of the NDSF.

The reported charter vessel catch of demersal scalefish in the waters of the Kimberley demersal fishery in 2014 was estimated to be 11.5 t (grass emperor – 1.9 t; golden snapper – 3.5 t; goldspotted/blackspotted rockcod – 1.0 t; saddletail snapper – 1.5 t; crimson snapper – 0.8 t). The Kimberley charter vessel catch is estimated to be ca. 1.0% of the Kimberley commercial catch of demersal fish.

Most of the recreational fishing effort targeting demersal finfish in the Kimberley region is concentrated in the Broome sector of Area 1, which is closed to commercial fishing on demersal species. The magnitude of recreational fishing catch in offshore areas is small relative to the total commercial catch.

Fishing effort/access level

Pilbara

Fishing effort utilisation by the trawl and trap sectors of the commercial fishery are monitored using VMS. Fishing effort for the trawl fishery is also recorded as the net bottom time (hours) in statutory logbooks. Information on fishing effort (days) for the trap and line fisheries are recorded in monthly catch and effort returns (North Coast Table 3).

The trawl fleet had the equivalent of three full-time vessels in the 2014/15 season. The percentage of allocated hours used by the trawl fleet during the 2014/15 season were 86% in Area 1, 95% in Area 2, 87% in Area 4 and 54% in Area 5. Trawling has not been permitted in either Area 3 or Area 6 since 1998 and both trap and line fishing has not been permitted in Area 3 since 1998 (North Coast Figure 1).

In 2014, trap fishers were allocated 5,456 trap days (capacity is set in trap days with a value per unit of 1 unit = 1 trap day), with 50% of the units used as calculated from the VMS.

In 2014, line fishers reported operating for 195 days, compared with 358 days in 2013.

Kimberley

The eight fish trap vessels that fished in the NDSF in 2014 reported using between 18 and 36 fish traps per day. Effort across all zones of the fishery in 2014 was 1,058 days (North Coast Table 8).

The total effort allocated in Zone B in 2014 was 986 standard fishing days (i.e. using 20 traps per day) (North Coast Table 8). The number of standard fishing days (SFDs) recorded in Zone B using VMS data was 897 SFD’s (91%). That is, 9% of effort allocated to Zone B in 2014 was not used. A total of 616 standard fishing days was allocated to Zone A. The number of SFDs recorded using VMS data was 153 (233 SFDs in 2013), indicating that ~75% remained unutilised in Zone A at the end of the season. The effort expended in Zone C in 2014 was 8 SFD’s.

Thus, latent effort exists in all Zones of this fishery.

Pilbara

There multiple tiers of assessment used in the Pilbara, that when combined constitute a weight-of-evidence approach to determine overall stock status based on the performance of indicator species that represent the entire demersal suite of species. The different tiers of assessment (see How to Use This Volume for more details) are applied to the various indicator species of this suite. Catch and catch rate analyses are used to assess five indicator species and the total retained catch on an annual basis. Fishing mortality estimates ($F$) derived from age structure data are used to assess red emperor, Rankin cod and bluespotted emperor relative to internationally recognised biological reference points (BRP) based on ratios of natural mortality ($M$) on a periodic basis with the last analysis completed using 2011 age structure data. An age-structured model incorporating catch rates, catch history and age structure data is used to assess spawning biomass levels for red emperor and Rankin cod also on a periodic basis with the last assessment completed in 2007.

---

1 The BRPs for long-lived (> 20 years) species include (1) the Target level, where $F \leq 2/3 M$, which indicates fishing has exceeded sustainable levels; and (2) Limit level, where $F = 1.5 M$, which indicates that fishing has greatly exceeded sustainable levels.
Catch Rates
Catch rates are derived from logbook catch data and adjusted according to the unload data, so that catches match reported unloads with the spatial (i.e. management areas) component obtained from logbooks. There are two measures of effort used to derive catch rates including the duration of the trawl shots as reported in logbooks and the time spent in each management area on each trip derived from VMS data. VMS data have only been available since 2000. Catch rates were calculated using the adjusted catch divided by effort (separately for both methods) by area for each trip. A moderate efficiency increase (0-4% per year) is applied to nominal catch rates based on trawl-time as this level of efficiency increase is typical for many trawl fisheries internationally.

Mean trawl catch rates of the indicator species and the total catches decreased each year from ca. 2004 to 2008 (North Coast Figure 2). From 2009-2011, the catch rates of the shorter lived indicator species (bluespotted emperor and brownstripe snapper) and total retained catch increased each year. From 2011-2014 the trends in catch rates for these shorter lived species and the total retained catch have remained stable or increased (North Coast Figure 2). The general trends in catch rates for the longer lived indicator species (red emperor, Rankin cod and goldband snapper) and total retained catch increased each year. From 2011-2014 the trends in catch rates for these longer lived species and the total retained catch have remained stable or increased (North Coast Figure 2). The shorter lived indicator species (bluespotted emperor and brownstripe snapper) and total retained catch have increased each year. From 2011-2014 the trends in catch rates for these shorter lived species and the total retained catch have remained stable or increased (North Coast Figure 2). The general trends in catch rates for the longer lived indicator species (red emperor, Rankin cod and goldband snapper) and total retained catch increased each year.

Fishing Mortality
The high rate of fishing mortality of red emperor (> BRP Limit level) in the western areas (Areas 1 and 2) of the trawl fishery (North Coast Table 4), and the declining catch rates of several species including the indicator species of red emperor and Rankin cod led to a reduction in effort of 16% in Areas 1 and 2 and 4% in Area 4 in 2009. This followed an industry agreed effort reduction in Area 1 in 2007 and 2008.

Age Structured Model
The age-based stock assessment models for the two indicator species, red emperor and Rankin cod, were last run in 2009 based on age data up to 2007. The outcomes of these model runs indicated that: 1) red emperor spawning biomass was greater than 40% of virgin biomass overall, with declining trends forecast for Areas 1 and 4 and stable forecast trends for Areas 2 and 5 for future years; and 2) Rankin cod spawning biomass was greater than 40% of virgin biomass overall, with a declining trend forecast for future years across most management areas. However, this assessment indicated that the spawning biomass for these indicator species of the Pilbara Demersal Fishery as a whole were above their target levels, indicating satisfactory breeding stock levels and a moderate risk of recruitment overfishing. These assessments were last run prior to effort reductions in the trawl fishery and the fishing mortality estimates from age structures of indicator species collected in 2007, 2008 and 2011. These age-based stock assessment models are scheduled to be updated following the completion of fishing mortality estimates derived from age structures of these indicator species collected in 2011.

Current Assessment
Following concerns for the sustainability of the Pilbara demersal scalefish resource based on; 1) declining trends in catch rates of all indicator species and the total catch from ca 2004-2008, and; 2) fishing mortality estimates that exceeded limit references levels for red emperor in Areas 1 and 2 in 2007, voluntary effort reductions were taken by the trawl industry in 2008 in Area 1 and implemented legislatively in 2009, in Areas 1, 2 (16% combined) and 4 (4%). This has resulted in the lowest historic levels of effort for the trawl fishery since the individual transferable effort system was introduced in 1998. It has been five years since these effort reductions were introduced and early signs of stock rebuilding are evident from stabilising or increasing catch rates of the shorter lived indicator species (bluespotted emperor and brownstripe snapper). These species are expected to display positive responses earlier than the longer lived indicator species (red emperor and Rankin cod) considering they are selected by the trap and trawl fisheries at a younger age (i.e. 2-3 vs. 5-6 years) and they have inherently higher population productivity. Since 2008 and following the implementation of effort reductions, the longer lived indicator species (red emperor and Rankin cod) have generally displayed stable catch rates in most management areas. If these longer-lived species are also recovering, it is expected that increases in catch rates will become evident from approximately 2014/15 onwards due to the lag between recruitment and vulnerability to the trawl fishery (5-6 years of age). Otoliths of the indicator species, red emperor, Rankin cod, bluespotted emperor, brownstripe snapper and ruby snapper were collected in 2011 from each management area of the trawl, trap and line fisheries. The age structures derived from these otolith collections will be used to evaluate changes in fishing mortality since previous estimates in 2007/08 and therefore the sustainability of current exploitation levels.

Pilbara: The major performance measures for the fish stocks in the Pilbara demersal fisheries relate to breeding stock levels of the long-lived indicator species, i.e. red emperor and Rankin cod. The target level of spawning biomass is 40% of the initial level when the catch was first recorded. The limit level is 30% of the initial spawning biomass. The spawning biomass levels of the target species were assessed as adequate (spawning biomass was greater than 40% of virgin biomass) in 2009 by synthesising the available data in an age-structured model.

Kimberley
Assessment of the indicator species in the NDSF is also undertaken using a multi-tiered approach. Catch and catch rates are assessed annually and an age structured stock assessment model is applied using relevant data on a periodic (5 year) basis with the last assessment completed in 2009. Age composition data for the next assessment was collected during 2012. The next assessment of the fishery is scheduled for 2015.

Catch Rates
The catch rate (or catch per unit of effort, CPUE) presented in this status report is a nominal catch rate statistic calculated as the annual mean of the landed catches divided by corresponding units of fishing effort expended within Zone B of the fishery, which is the traditional core area fishing activity. Effort is adjusted for gear type used (based on standard fishing days). Nominal CPUE from data recorded on monthly catch and effort returns (1998-2008) were calculated as the sum of landed catches divided by total

STATUS REPORTS OF THE FISHERIES AND AQUATIC RESOURCES OF WESTERN AUSTRALIA 2014/15 195
standard fishing days reported by each vessel in each month. Nominal CPUE from data recorded on daily trip returns (from 2010 onwards) were calculated as the landed catch divided by the total standard fishing days reported for each trip. For the 2009 reporting year, since some vessels had not yet switched to reporting their catch and effort on daily trip returns, the annual mean CPUE was calculated as the mean of monthly and trip CPUEs weighted by effort.

Nominal catch rates for Zone B only are presented in North Coast Figures 4-6, as this area represents the historical core fishing area of the NDSF prior to zoning in 2006. During 2014, Zone B catch rates for the indicator species were 139 kg/std day for red emperor, 500 kg/std day for goldband snapper and 205 kg/std day for cods/groupers. Catch rates for red emperor in 2014 are slightly higher than those reported in 2012 and 2013 (125 and 120 kg/std day, respectively), while the catch rate for the cods/groupers is the highest reported, exceeding the 2012 catch rate of 198 kg/std day. The catch rate for goldband snapper in 2014 was similar to that reported in 2012 and 2013.

The 2014 catch of goldband snapper, red emperor and the cods/groupers from all zones were all close to the average of the previous four years, hence none exceeded the ESD trigger point of a 20% increase in catch above the average of the past four years. Increases in catch levels are, by themselves, not very sensitive indicators of stock status but combined with the previous estimates of fishing mortality of goldband snapper being close to the upper acceptable limit, further material increases in their catch would represent an unacceptable risk given the information currently available. While several scenarios may explain the increased catches of goldband snapper in recent years, their validity should be resolved following the next collection and analysis of the representative age samples. Marriott et al. 2014 examined catch rate data for goldband snapper and red emperor. For goldband snapper, standardised catch rates displayed an increasing trend, although the underlying cause could not be determined. As such, the standardised index for goldband snapper should be used with caution. In contrast, the standardised index generated for red emperor is the best available indication of historical trends in abundance for that stock and therefore should be used for future stock assessments. The results of this work will be incorporated in the next stock assessment advice.

Age Structured Model

The spawning biomass of the key target species in the NDSF was last estimated by an age-structured stock assessment model using age data collected prior to 2007, which indicated the spawning biomass was above the international target reference point of 40% of virgin biomass but with a slight declining trend for both red emperor and goldband snapper. These model outputs were reviewed by Prescott and Bentley in 2009, who concluded that the model was appropriate for use but would benefit from modifications, including the better determination of levels of model uncertainty. The model is currently being updated with continuous ongoing improvements being undertaken ahead of the next assessment.

Current Assessment

The most recent model based assessment estimates indicated that there was a high probability that the spawning stocks of the indicator species were both above their respective threshold levels at that time. The overall catch levels and the species based catches were all within the acceptable ranges for the fishery, noting significant increases in goldband catches since 2007. The catch rates for the indicator species were either stable or declining gradually and the F based assessments indicated that the fishing level on the indicator species were either lower than the target level or between target and threshold levels. Consequently the stocks for the suite of species targeted by this fishery are effectively fished and currently considered to be at acceptable levels. If catches in Zone B are maintained at current levels, there is a low likelihood that the spawning stocks of any species within this suite declining to unacceptable levels. The current risk to sustainability for this suite is therefore at acceptable levels. Zone A of the fishery continues to receive significant levels of effort and catch. There is currently only a low to moderate risk to the sustainability of the fishery resources in this zone. Zone C of the fishery received a negligible level of effort in 2014. Therefore, there is currently a very low risk to the sustainability of the fishery resources in this zone.

NDSF: The performance measures for this fishery relate to the maintenance of adequate breeding stocks for the key indicator species as indicated by the catch levels. In 2014, the catch of both goldband snapper and red emperor were similar to that reported in 2013, and both were below the performance indicator of a 20% increase in catch above the average catch of the preceding four years. The 2014 level of catch of cods/groupers complex was below that landed in 2013, and also did not exceed the performance indicator of a 20% increase in catch above the average catch of the preceding four years. Combined with the spawning biomass for both red emperor and goldband snapper having been assessed as greater than 40% of virgin biomass in 2009, all species/groups are considered to currently have adequate breeding stock levels.

Non-Retained Species

Bycatch species impact:

**Pilbara**

Low - Moderate

**Kimberley**

Low

**Pilbara**

Species of teleosts caught as bycatch by the trawl fishery are typically small bodied and/or short lived. Such species are considered less vulnerable compared to longer-lived teleost species based on their population production potential. Thus, the indicator species used in the weight-of-evidence stock assessments for the Pilbara demersal scalefish resources are considered to provide an adequate indication for similar or less vulnerable retained and bycatch species. In 2010, an ecological assessment of fish assemblages and habitat characteristics in trap, trawl and a 12 year targeted fishery closed area was undertaken. The results of this study are being collated.

An intense six month observer program was completed in the last half of 2012 that investigated catch rates and subsurface expulsion rates in trawl nets. This program used dual-lens above water and subsurface within-net, secure camera systems to achieve a high level of observer coverage on all...
trawl vessels operating in the Pilbara fishery (n = 3). Observer coverage rates of 85.2% of trawl catches above water (n = 1,916 trawls observed), and 71.7% of day-trawls (n = 774 trawls observed) and 53.9% day-trawl hours (n = 1,013 h observed) below water, were achieved. Overall, 38.1% of megafauna exited through escape hatches in nets during trawling in rapid time (91.2% in < 5 minutes). About two thirds of all chondrichthyans were expelled from escape hatches during trawling, with the majority expelled relatively quickly (< 10 min). This resulted in more than half of the trawl catches containing no chondrichthyan bycatch (51.4%).

The Pilbara Fish Trawl Interim Managed Fishery was re-accredited a Wildlife Trade Operation (WTO) under the Commonwealth of Australia’s Environmental Protection and Biodiversity Conservation (EPBC) Act for three years from mid-2014. This included specific conditions around the observing, reporting and mitigation of endangered, threatened and protected species interactions. As such, an ongoing 12 month independent electronic observer program will be conducted during this accreditation period.

The fish trap and line fisheries have minimal bycatch (see Kimberley below).

**Kimberley**

As a result of the catching capacity of the type of gear used and the marketability of most species caught, there is a limited quantity of non-retained bycatch in this fishery. The most common bycatch species is the starry triggerfish (*Abalistes stellaris*), but the numbers taken are not considered to pose a significant risk to the sustainability of this species.

**Listed species interaction:**

<table>
<thead>
<tr>

<th>Pilbara</th>
<th>Kimberley</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low - Moderate</td>
<td>Low</td>
<td>Negligible</td>
</tr>
</tbody>
</table>

**Pilbara**

The Pilbara Fish Trawl Fishery (PFTF) has a long history of developing and adopting mitigation measures that have resulted in very low capture rates of endangered, threatened and protected (ETP) megafauna, i.e. dolphins, turtles, sea snakes and sawfish. However, there has been uncertainty over the potential for unaccounted mortality of ETP megafauna from subsurface expulsion through escape hatches in the trawl nets (particularly air breathing species). To examine this issue, all trawl operations in the fishery (n = 3) were fitted with dual-lens above water and subsurface within-net, secure camera systems. This resulted in a high level of observer coverage from June to December 2012 that far exceeded that stipulated in the Bycatch Action Plan (22%) and levels achieved from previous studies from the PFTF. Capture rates of ETP megafauna were very low. All observed catches of ETP species were reported in statutory logbooks and these catch rates were consistent with previous data since exclusion grids were mandated in March 2006. Therefore, there was no evidence to suggest that captures of ETP species were being unreported by commercial fishers. The subsurface expulsion of megafauna in poor condition was extremely rare (only one dolphin was observed from over 1,000 trawl hours of within-net observations) and thus reporting rates in statutory logbooks are likely to be close to census. Extensive subsurface observations determined that current mitigation strategies are highly effective for sea snakes and turtles, and that further mitigation strategies in the forward sections of trawl nets would likely be more effective for dolphins and sawfish. Nonetheless, catch rates of dolphins were very rare (5.2 per 1,000 trawls) and had decreased by 20-60% from previous estimates (i.e. 12.6 from observers or 6.5 from logbooks per 1,000 trawls from 2003-2009) despite continued high levels of dolphin attendance and depredation (> 75% of trawls). The very low levels of mortalities of these ETP megafauna by the PFTF were considered to pose a negligible risk to their sustainability based on 1) these levels are likely to be less than their natural mortality rates (e.g. at least 371 bottlenose dolphins stranded in Western Australia from 1981-2010, 2) they appear abundant in Western Australian waters despite large scale mortalities from historic foreign fishing (e.g. 13,459 cetacean mortalities from Taiwanese fishing from 1981-86), and 3) they have wide distributions and are highly mobile. The outcomes of this observer program were reported in Fisheries Research Report 244, published in 2014. In 2014, the Pilbara trap fishery reported 114 sea snake interactions. Sea snakes are returned to the water alive.

**Kimberley**

Using trap gear in continental shelf regions is very unlikely to interact with listed species. Recent video observations indicate that the potato cod (*Epinephelus tukula*), a totally protected species, can be present in high numbers at discrete locations within the fishery. Potato cod rarely enter traps due to their large size and girth limiting their capacity to pass through the entrance funnel into the traps. One potato cod (*Epinephelus tukula*) was reported in the Kimberley (NDSF) in 2014, and was released alive.

In 2014, the Kimberley trap fishery reported 124 sea snake interactions. Sea snakes are returned to the water alive.

**Ecosystem Effects**

**Food chain effects:**

<table>
<thead>
<tr>
<th></th>
<th>Pilbara</th>
<th>Kimberley</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low</td>
<td>Negligible</td>
<td></td>
</tr>
</tbody>
</table>

**Pilbara**

The Pilbara Fish Trawl Interim Managed Fishery operates with standard stern trawling gear (single net with extension sweeps) within an area previously trawled by foreign vessels. Previous research by CSIRO has suggested that the extensive Taiwanese pair Trawl Fishery caused a significant decrease in the biomass of finfish on the North West Shelf, and a
change in species composition towards smaller (shorter lived) species. The current WA Fish Trawl Fishery, which developed when the fish stocks had begun to recover, uses a much larger mesh size and much lighter ground gear, and operates at lower exploitation rates and only in restricted parts of the continental shelf. At the present levels of catch and effort by the fish trawl, fish trap, and line fisheries, the broader effect on the trophic levels and community structure of the North West Shelf is considered to be at an acceptable level. Hall and Wise (2011) demonstrated that there has been no reduction in either mean trophic level or mean maximum length in the finfish catches recorded within the Pilbara (i.e. no fishing down of the food web) over the past 30 years.

**Kimberley**

The need to maintain relatively high levels of biomass for the species caught in this fishery to meet stock recruitment requirements results in a negligible risk to the overall ecosystem from the fishery. Hall and Wise (2011) demonstrated that there has been no reduction in either mean trophic level or mean maximum length in the finfish catches recorded within the Kimberley (i.e. no fishing down of the food web) over the past 30 years.

**Habitat effects:**

<table>
<thead>
<tr>
<th>Region</th>
<th>Impact</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pilbara</td>
<td>Moderate</td>
</tr>
<tr>
<td>Kimberley</td>
<td>Low</td>
</tr>
</tbody>
</table>

**Pilbara**

Direct impacts to the habitat are limited to those of the Pilbara Fish Trawl Interim Managed Fishery, which is restricted to less than 5% of the North West Shelf (North Coast Figure 1). Area 3 and the waters inside the 50 m isobath are permanently closed to fish trawling, Zone 1 is closed to fish trawling, and Area 6 has had no fish trawl effort allocation since 1998.

Within the areas actually trawled, past research has indicated that approximately 10% of the sessile benthic fauna (e.g. sponges) are detached per year. It is not known whether the detachment rate exceeds the rate of re-growth. Considering effort for the trawl fishery is at historically low levels and the effective area trawled within the managed areas has been greatly reduced, it is likely that the trawl fishery imposes a moderate risk to the small amount of habitat in the Areas open to trawling (5% of NWS) but a negligible risk to the total habitat in the North West Shelf.

**Kimberley**

As a result of the gear design, the fishery has little impact on the habitat overall, although there may be some rare interactions with coral habitats which are not common in areas where the fishery operates.

---

**Social Effects**

**Pilbara**

It is estimated that 14 fishers on 3 vessels were directly employed during 2013 in the Pilbara Fish Trawl Fishery, and 8 fishers on 3 vessels in the Trap Fishery, and at least 21 fishers on 7 vessels in the line fishery. Overall, at least 41 people were directly employed in the Pilbara Demersal Scalefish Fisheries. This fishery supplies significant amounts of fish to Perth, with catches from the Pilbara fisheries dominating the Perth metropolitan markets and supporting the local fish-processing sector. The exports from this fishery have been minimal in the last few years due to the increased value of the Australian dollar.

**Kimberley**

Eight vessels fished in the 2014 fishing season, indicating at least 24 people (assuming ~3 crew per vessel) were directly employed in the NDSF. Approximately half the fish from this fishery are supplied to Perth metropolitan markets, while the other half is supplied to east coast metropolitan markets.

**Economic Effects**

**Estimated annual value (to fishers) for 2013-14:**

<table>
<thead>
<tr>
<th>Region</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pilbara</td>
<td>Level 3 - $5 - 10 million</td>
</tr>
<tr>
<td>Kimberley</td>
<td>Level 3 - $5 - 10 million</td>
</tr>
</tbody>
</table>

The value of each of the North Coast Demersal fisheries is individually reported using the 6 categories defined in Fletcher et al. (2010) used to assess the relative economic (based on gross value product, GVP) and social amenity values associated with each regional level ecological asset. These values are based on GVP figures derived from the 2012-2013 financial year.

**Pilbara**

The fish trawl demersal scalefish catch is dominated by lower-valued species such as bluespotted emperor and threadfin bream, and its value is estimated to be Level 2 – $1-5 million. For social amenity some of the species may be caught recreationally and/or there is some specific interest in the asset by the broader community. The fish trap and line catches are dominated by valuable species such as red emperor and goldband snapper, and the demersal scalefish catch from these sectors was estimated to have an economic value of $1-5 million and the social amenity is also Level 2. For the line fishery the economic value is Level 1 < $1 million and social amenity is minimal because there is no recreational fishing for these offshore species and no specific broader community interests.

**Kimberley**

The NDSF principally targets the higher-value species such as the goldband snapper and red emperor resulting in an economic value of $5-10 million. The social amenity value is that this is an important asset locally.

---

**Pilbara: The performance measure for the fish trawl impact on the North West Shelf habitat was set as a maximum area of operation by the trawlers. With the current closures within the licensed area of the fishery (50 m to 200 m depth), 46% of the area is accessible to the trawl vessels. Plots of trawl activity from VMS data indicate the actual area trawled is significantly less than this.**

</tr>
<tr>
<td>Kimberley</td>
<td>Acceptable</td>
</tr>
</tbody>
</table>

Pilbara

In the Fish Trawl Fishery, the total catch was still well below the target catch range continuing a trend of the last eight seasons. Considering, 1) catch rates of indicator species are stable or increasing for shorter lived species since effort reductions; 2) effort within the trawl fishery is currently at historically low levels, and 3) results from a higher level fishing mortality-based stock assessment and ecosystem based ecological assessment will be available in 2015 and 2016; current levels of effort and catch in the Pilbara fish trawl fishery are considered to impose a moderate risk for stock sustainability for the Pilbara Demersal Scalefish resource.

In the Fish Trap and Line Fisheries, the total catch was below the target catch ranges in 2014 due to less effort.

Kimberley

For the 2014 calendar year, the total allowable effort was set at 616 standard fishing days in Zone A, 985.6 fishing days in Zone B and 1,100 fishing days for Zone C. The Zone A and C allocation aims to facilitate the exploration and development of this area of the fishery. At these levels of total effort and at recent catch rates, the total catch of the fishery is expected to be in the range of 600–1,000 t. The 2014 catches were above the reported range. However, given the recent increases in fishing effort in Zone A, there is a need to review the target catch range for this fishery.

In addition to the overall catch target, ESD performance measures state that the annual catch of each of the key target species/groups (red emperor, goldband snapper and the cod/grouper complex) taken by the fishery should not increase by more than 20% above the average for the previous four years. Of the key target species/groups, none were above the average of the previous four years, or exceeded the ESD performance measure. Catches of goldband snapper, red emperor and the cods/groupers complex remained below the trigger level.

New management initiatives (2015)

Pilbara

In 2015, the Department will work with permit holders in the Pilbara Fish Trawl Interim Managed Fishery to adhere to the conditions of the re-accredited Wildlife Trade Operation approval; this will include the development of a logbook validation program, through electronic monitoring.

The Department will continue to review the Pilbara Fish Trawl Interim Management Plan, in 2015.

Kimberley

In 2015, the Department will undertake a Level 5 Stock Assessment of the indicator species in the NDSF. This advice will be used to determine effort allocations for future years in consultation with industry.

The Northern Demersal Scalefish Fishery Operators Guide to the Management Arrangements 2015 (Fisheries Occasional Publication No 120) was published in April 2015, and is a plain English guide to the management arrangements, designed to assist licence holders.

External Factors

The Commonwealth’s North-west Marine Bioregional Plan incorporates the aim of introducing marine reserves, which are likely to contain areas closed to fishing. This has the potential to restrict access to fishing in parts of the North Coast Bioregion to all sectors, i.e. commercial, recreational and charter.

Under the Offshore Constitutional Settlement, commercial trawl vessels licensed by the Commonwealth may operate in waters outside of a line that is meant to represent the 200 m isobath as part of the North West Slope Trawl Fishery (NWSTF).

Climate change and climate variability has the potential to impact fish stocks in a range of ways including influencing their geographic distribution (e.g. latitudinal shifts in distribution). However, it is unclear how climate change may affect the sustainability risk to North Coast demersal fisheries.

The North Coast demersal fisheries underwent MSC pre-assessment in 2014. Outcomes from the pre-assessment are currently under review.

Pilbara

The available fishing area has decreased slightly over recent years as a result of exclusion zones for gas pipelines and associated facilities. Seismic surveys also restrict the operation of fishers. However, there is little information as to the impacts and therefore the risks from seismic operations on demersal scalefish.

Kimberley

The impacts of environmental variation on the fishery are not considered to be large as target species are long-lived and inter-annual variability is likely to be ‘smoothed’. Some commercial fishers within the fishery have raised concerns about the increasing numbers of charter vessels operating in the offshore waters of the NDSF, which could generate resource-sharing issues in the future. In addition, offshore developments in the energy/gas industry may involve exclusion zones thus potentially limiting fisher access to some areas of the fishery. Increasing development of the Kimberley region is also likely to see a marked increase in the recreational effort and this may impact on stock sustainability.

NORTH COAST FIGURE 1
Demersal scalefish fisheries of the North Coast Bioregion of Western Australia. In the Pilbara subregion: Areas 1 to 6 refer to the management regions in Zone 2 of the trawl fishery. Zone 1 has been closed to trawling since 1998. In the Kimberley subregion: Zones A, B and C lie in Area 2 of the NDSF.
NORTH COAST FIGURE 2

Annual mean Catch Per Unit Effort (CPUE, kg/hour) for five indicator species and the total catch in Areas 1, 2, 4 and 5 of the Pilbara Trawl Fishery from 1993–2014. The solid grey line is nominal annual catch rate (±1 se) with trawl time as the effort measure, the dashed black line is that catch rate incorporating efficiency increase (trawl time as the effort measure) and the solid black line is annual catch rate using the time spent in each area as the effort measure (derived from VMS, data available since 2000).
NORTH COAST FIGURE 3
Catch levels of demersal finfish in the NDSF by line and trap from 1998–2014. Note that prior to 2006 the NDSF was not differentiated in zones. Since 2006 catches are reported separately by zones within Area 2 of the fishery. The dashed lines represent the acceptable catch range of 600-1000 tonnes for the fishery.

NORTH COAST FIGURE 4
Catch, effort and catch per unit of effort of red emperor in the NDSF by trap, 1998–2014 (2006-2014 for Zone B only, catches represent total landings in B Zone, whereas effort and catch rate (CPUE) are determined from commercial vessel activity only). The catch rate (CPUE) presented here is a nominal catch rate that is calculated as the mean of monthly fleet catches divided by effort adjusted for gear type within Zone B of the fishery only, except for data from daily trip returns, where catch rates are calculated as the mean of all catch rates attained during separate fishing trips. Standard error bars illustrate variability in CPUE from the two sources of catch returns in 2009, and variability in trip CPUE data from daily logbooks (2010-14).
NORTH COAST FIGURE 5
Catch, effort and catch per unit of effort of goldband snapper in the NDSF by trap, 1998–2014 (2006-2014 for Zone B only, catches represent total landings in B Zone, whereas effort and catch rate (CPUE) are determined from commercial vessel activity only). The catch rate (CPUE) presented here is a nominal catch rate that is calculated as the mean of monthly fleet catches divided by effort adjusted for gear type within Zone B of the fishery only, except for data from daily trip returns, where catch rates are calculated as the mean of all catch rates attained during separate fishing trips. Standard error bars illustrate variability in CPUE from the two sources of catch returns in 2009, and variability in trip CPUE data from daily logbooks (2010-14).

NORTH COAST FIGURE 6
Catch, effort and catch per unit of effort of the cod/grouper complex in the NDSF by trap, 1998–2014 (2006-2014 for Zone B only, catches represent total landings in B Zone, whereas effort and catch rate (CPUE) are determined from commercial vessel activity only). The catch rate (CPUE) presented here is a nominal catch rate that is calculated as the mean of monthly fleet catches divided by effort adjusted for gear type within Zone B of the fishery only, except for data from daily trip returns, where catch rates are calculated as the mean of all catch rates attained during separate fishing trips. Mackerel Managed Fishery Report: Statistics Only

B. Molony, E. Lai and R. Jones

Fishery Description

Commercial
The Mackerel Fishery uses near-surface trolling gear from vessels in coastal areas around reefs, shoals and headlands to target Spanish mackerel (*Scomberomorus commerson*). Jig fishing is also used to capture grey mackerel (*S. semifasciatus*), with other species from the genera *Scomberomorus, Grammatorcynus* and *Acanthocybium* also contributing to commercial catches.

Recreational
Recreational fishers target similar species using a range of gears including trolling, shore-based drift fishing with balloons and spear guns.

Governing legislation/fishing authority

Commercial
* Mackerel Managed Fishery Management Plan 2011
* Mackerel Managed Fishery Licence

Recreational
* Fish Resources Management Act 1994; Fish Resources Management Regulations 1995 and other subsidiary legislation

Boundaries

Commercial
The Fishery extends from the West Coast Bioregion to the WA/NT border, with most effort and catches recorded north of Geraldton, especially from the Kimberley and Pilbara coasts of the Northern Bioregion. Catches are reported separately for three Areas: Area 1 - Kimberley (121° E to WA/NT border); Area 2 - Pilbara (114° E to 121° E); Area 3 - Gascoyne (27° S to 114° E) and West Coast (Cape Leeuwin to 27° S) (Spanish Mackerel Figure 1).

Recreational
The fishery operates between the West Coast Bioregion and the WA/NT border, with most activity occurring between Perth and Dampier.

Management arrangements

Commercial
The Fishery transitioned from an interim managed fishery to a managed fishery on 1 January 2012. The Mackerel Managed Fishery (MMF) operates under an Individual Transferable Quota (ITQ) system which includes the setting of Total Allowable Commercial Catches (TACCs) for each Area of the Fishery, allocation of the entitlement to take quota in the form of units, and establishment of minimum unit holding requirements to operate in the Fishery.

The maximum quantity of mackerel that may be taken from each Area of the Fishery during any licence period (1 January to 31 December) is limited to the quantity of mackerel determined within the Management Plan. The TACC for each Area of the Fishery for 2014 was:

<table>
<thead>
<tr>
<th>Area</th>
<th>Spanish and other mackerel</th>
<th>Grey mackerel</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>205 t</td>
<td>60 t</td>
</tr>
<tr>
<td>2</td>
<td>126 t</td>
<td>60 t</td>
</tr>
<tr>
<td>3</td>
<td>79 t</td>
<td>60 t</td>
</tr>
</tbody>
</table>

The Plan includes limitations on the number of licences to fish in the Fishery and the type of gear that can be used. Boats operating in the Fishery are monitored by VMS and the master of an authorised boat is required to submit logbook returns and catch and disposal records. Seasonal closures were removed in May 2008, as they were no longer a necessary tool to maintain sustainable and efficient management of the Fishery after quotas were put in place in 2006.

Licence holders may only fish for mackerel by trolling or handline. There are currently 48 licences in the Fishery with 14, 16 and 18 licences in Areas 1, 2 and 3 (respectively), with the combined quota allocations being consolidated onto 14 boats operating within the fishery.

A comprehensive ESD assessment of this Fishery determined that levels of Spanish mackerel breeding stock should be used as an annual performance measure for the Fishery. In November 2014, the Fishery received a one year extension to the 2009 exemption from the export controls of the *Environment Protection and Biodiversity Conservation Act 1999* for a period of five years.

Recreational
Since 2 March 2010, all persons fishing from a powered boat anywhere in the state have been required to hold a Recreational Fishing from Boat Licence or fish in the company of a licence holder. The Recreational Fishing from Boat Licence provides a state-wide database of recreational boat fishers that can be utilised for survey purposes.

A revised statewide combined daily bag limit of three Spanish mackerel and grey mackerel was introduced in 2013 as an outcome of the statewide recreational fishing review. Previously a combined daily bag limit of two in the West Coast and South Coast Bioregions and four in the Gascoyne and North Coast Bioregions applied.

</tbody>
</table>

Commercial
A total of 11 boats operated in 2014, with three, four and seven vessels operating in the Kimberley, Pilbara and Gascoyne/South Management Areas (Spanish Mackerel Figure 2), noting that some vessels operated in more than one...
management area. A total of 673 fishing days of effort were reported targeting Spanish mackerel in 2014, with more than 53% of effort days reported from the Kimberley Area. The majority of the catch is taken in the Kimberley Area, reflecting the tropical distribution of mackerel species (Spanish Mackerel Figure 2). Estimates of catches are monitored through mandatory logbook systems with the total catch of Spanish mackerel in the 2014 season estimated at 322.0 t which is similar to the levels that have been taken in this fishery (averaging about 300 t) since quotas were introduced in 2006 (Spanish Mackerel Figure 2).

A total of 4.6 t of other species of mackerel were landed in the 2014 season, including 3.5 t of grey mackerel. The catch of grey mackerel in 2014 was of a similar magnitude to grey mackerel catches by the fishery since 2006 but well below the TAC and the historical high catches of ‘other mackerel’ (which included grey mackerel until 2006) recorded in the late 1980s and 1990s. All commercial estimates reported do not include fish caught and released or lost to sharks.

Recreational

Estimates of recreational catches of Spanish mackerel were generated from data collected in the integrated survey of boat-based recreational fishing in WA conducted during 2011/12 and 2013/14. Estimates are available at the level of individual Bioregions (Spanish Mackerel Table 1). A total of 59.3 t of Spanish mackerel were landed by recreational boat-based fishers in 2013/14, with most (28.6 t) landed in the Gascoyne Coast Bioregion. An additional 47.3 t were captured and subsequently released. The total landed and released is similar to the estimates from the 2011/12 survey, although higher catches of Spanish mackerel were landed by recreational fishers in the Gascoyne in the 2013/14 survey.

Recreational anglers also reported small catches of other mackerel, including blue mackerel (Scomber australasicus), grey mackerel (Scomberomorus semifasciatus), school mackerel (Scomberomorus queenslandicus), shark mackerel (Grammatecynus bicarinatus), spotted mackerel (Scomberomorus munroi) and wahoo (Acanthocybium solandri). Recreational anglers also reported small amounts of unidentified mackerel. The next Statewide integrated survey of boat-based recreational fishing in WA is planned to collected recreational data during 2015/16.

Reported annual catches of Spanish mackerel by recreational charter boats are relatively minor. In 2014, a total of 14.9 t of Spanish mackerel were reported by Charter boat operators with an additional 7.4 t captured and released (Spanish Mackerel Table 1).

Fishery Governance

Target commercial catch range: 46 – 410 tonnes

The total catch in 2014 of 322.0 t was within the acceptable catch range for the Fishery. The reported catch from the Kimberley Area of 193.8 t was within the Area’s acceptable catch range (110 – 205 t), and within the range reported since 2005, albeit approaching the TAC for this Area. Catches in the Pilbara Area have been relatively stable since 2006, with the 2014 catch of 94.2 t (acceptable catch range 80 – 126 t). Catches from the Gascoyne/West Coast Area in 2014 were 34.1 t, below the acceptable range of 56 – 79 t but similar to the range of catches from this Area since 2004.

Current Fishing (or Effort) Level: Acceptable

Fishing effort throughout the Fishery has been relatively stable since 2006 following reductions due to management changes (Spanish Mackerel Figure 2). The high catch rates for the two main (Northern and Pilbara) fishery areas, both near record levels, indicates a relatively high abundance of Spanish mackerel in these management Areas (Spanish Mackerel Figure 3). Catch rates in the Gascoyne/West Coast have remained stable at relatively high levels for this Area since 2007.

As the minimum legal size for Spanish mackerel is 900 mm total length, similar to the size at maturity for this species, the spawning stock is essentially the same as the exploited stock. Therefore the status of the Spanish mackerel spawning stock is assessed based on the nominal catch rates for each Area of the Fishery. As catch rates are either continuing to increase or are stable at relatively high levels within each management Area, this suggests that the overall spawning stock is stable or increasing. Additionally, the total catches of Spanish mackerel remain within the target range of the Fishery.

Spanish mackerel in Western Australia is not considered to be recruitment overfished, and the level of fishing mortality is unlikely to cause the biological stock to become recruitment overfished.

Grey mackerel catch levels in the Mackerel Managed Fishery from 2000 to 2014 have been relatively low and stable, ranging between 10 and 24 t, with catches only reported from a small area within their range. However, the 2014 catch of 3.4 t is the lowest since 2000 and well below the TAC for grey mackerel. As the Fishery is not targeting grey mackerel to a great extent, the low catch in 2014 is not likely a cause for concern. Thus, grey mackerel in Western Australia is not considered to be recruitment overfished, and the level of fishing mortality is unlikely to cause the biological stock to become recruitment overfished.

New management initiatives (2015)

A review of the nomination requirements with the Fishery will occur in 2015/16. Following this an operator’s guide will be developed for licence holders and skippers to enhance their understanding of the management arrangements for the fishery.

The Mackerel Managed Fishery underwent pre-assessment for Marine Stewardship Certification in early 2014.
SPANISH MACKEREL TABLE 1
Recreational boat-based catch estimates (in tonnes, t) of Spanish mackerel in Western Australia 2013/14. Estimates are based on an average weight of a Spanish mackerel of 8.2 kg for the North Coast and 6.9 kg for other Bioregions. Too few Spanish mackerel were reported from the South Coast Bioregion during 2013/14 to generate a robust estimate.

Fishery Description

The Western Australian pearl oyster fishery is the only remaining significant wild-stock fishery for pearl oysters in the world. It is a quota-based, dive fishery, operating in shallow coastal waters along the North-West Shelf.

The harvest method is drift diving, in which six to eight divers are attached to large outrigger booms on a vessel and towed slowly over the pearl oyster beds, harvesting legal-sized oysters by hand as they are seen. The species targeted is the Indo-Pacific, silver-lipped pearl oyster (Pinctada maxima).

Governing legislation/fishing authority

Pearling Act 1990
Pearling (General) Regulations 1991
Commonwealth Government Environment Protection and Biodiversity Conservation Act 1999 (Export Exemption)

Consultation process

The Department undertakes consultation directly with the Pearl Producer’s Association (PPA) and licensees on operational issues. Formal licence holder engagement is convened by the West Australian Fishing Industry Council (WAFIC) under a Service Level Agreement with the Department.

Boundaries

The fishery is separated into 4 zones (Pearl Figure 1), as follows:

**Pearl Oyster Zone 1**: NW Cape (including Exmouth Gulf) to longitude 119°30’ E. There are 5 licensees in this zone.

**Pearl Oyster Zone 2**: East of Cape Thouin (118°20’ E) and south of latitude 18°14’ S. The 9 licensees in this zone also have full access to Zone 3. This zone is the mainstay of the fishery.

**Pearl Oyster Zone 3**: West of longitude 125°20’ E and north of latitude 18°14’ S. The 2 licensees in this zone also have access to Zone 2.

**Pearl Oyster Zone 4**: East of longitude 125°20’ E to the Western Australia/Northern Territory border. Although all licensees access this zone currently, exploratory fishing has shown that stocks in this area are not economically viable. However, pearl farming does occur. There is also a ‘buffer zone’ between zones 1 and 2, which may be accessed by licensees from both Zones, although in practice, it is generally only utilised by Zone 1 licensees.

Management arrangements

The Western Australian pearl oyster fishery is managed primarily through output controls in the form of a total allowable catch (TAC) divided up into individually transferable quotas (ITQs). There are 572 wild-stock ITQ units allocated across three management zones (Zone 1 – 115; Zone 2 & 3 – 457). Hatchery production is also controlled by ITQs; currently there are 350 hatchery ITQ units allocated. These wildstock and hatchery ITQ units are allocated amongst a total of 14 licences.

The value of a hatchery quota unit is 1,000 shell. The value of wild-stock quota units varies, depending on the status of wild stocks in each management area. Between 2008 and 2011 it was set at historically high levels (3,500 shell in 2011) in Zone 2&3 due to increased stock abundance. The ‘culture-sized’ (or 100 – 174 mm) wild stock quota unit for Zone 2/3 for the 2014 season was 1,100 shell, as a result of stock levels returning from record high levels to normal levels (Pearl Figure 2). In addition, a voluntary quota for ‘MOP’ only (oysters ≥ 175 mm) of 528 shells per unit was agreed to, resulting in a total unit value of 1,628 shells per unit. The Zone 1 wild stock quota unit remained at 478 shell per unit.

Wild stocks are reviewed each year by the Department of Fisheries to enable the TAC to be set for each zone of the fishery. The trial of the minimum legal size of 100 mm shell length was extended in 2014, to include the 2015-2016 seasons. Historically the legal size limit has been 120 mm shell length, and maximum legal sizes and area-specific TACs have been set where appropriate (e.g. in Exmouth Gulf in Zone 1).
A comprehensive Ecologically Sustainable Development assessment of this fishery has been undertaken to identify any potential sustainability risks requiring direct management. The only issue identified through this process related to the breeding stock levels of pearl oysters. Boxed text in this status report provides the annual assessment of performance for this issue.

The Pearl Oyster Fishery was re-assessed in 2013 under the Environment Protection and Biodiversity Conservation Act 1999 and is currently exempt from export controls under the List of Exempt Native Species until December 2018.

Stock Assessment

**Assessment complete:** Yes

**Assessment level and method:** Level 3

**Catch rate predictions, standardised CPUE**

**Breeding stock levels:** Adequate

A stock assessment of the *Pinctada maxima* fishery was undertaken for the 2014 fishing season based on catch and effort statistics, settlement analysis (38,000 shell sampled for ‘piggyback’ spat to obtain estimates of age 0+ and 1+ relative abundance), length-frequency sampling (4,200 shells measured), shell discard rates by size and location, population dive surveys, and an evaluation of the predictive capacity of 0+ and 1+ spat settlement data.

These were used to generate trends in stock indicators, from which the assessment of the TAC for 2015 was undertaken and provided to the Stock Assessment Working Group (SAWG). The SAWG is a Department-Industry group that provides integrated advice to the Director General on the sustainable harvest of the pearl oyster resource. The results for each zone, and issues relevant to stock sustainability were:

**Zone 2/3:** The culture-shell catch rate achieved by the fishery is an indicator of the abundance of the 3/4 to 6/7-year-old oysters specifically targeted for pearl production. Year-to-year variations reflect changes in recruit abundance, while the long-term trend in catch per unit effort (CPUE) involves an element of effort efficiency change. A standardised SCPUE index has been developed and provides the best estimate of annual abundance accounting for environmental and efficiency effects as well as the change in minimum size. SCPUE in 2014 was 28 shells per hour, the same as in 2013, which is at the lower end of the target range, but still above the threshold SCPUE (Pearl Figure 3). Raw CPUE was 38 shells per dive hour, a similar level to 2013 and 2012 (35 and 36 shells per dive hour respectively; Pearl Figure 3). This stabilisation of catch rate indicates that stock levels have returned to normal levels after record high levels in 2008 - 2011 as a result of good spat settlement in 2005. The MOP catch rate of 104 shell per hour in 2014 was similar in 2013 at 112 shell per hour and much higher than the 72 shell per hour in 2012.

**Catch rate prediction:** Recruitment to the Zone 2/3 fishery, as measured by the standardised catch rate (SCPUE), is predicted by the piggyback spat abundance index at 4 to 6 years prior to the current fishing year. The predicted recruitment is then used to set the quota for forthcoming years according to the harvest control rule (Pearl Figure 4). A very high 0+ spat abundance detected in the Zone 2 fishery in 2005 was confirmed in the 1+ spat year class in 2006, and again in the 2+ age class from population surveys in 2007. This cohort entered the commercially fished population between 2009 and 2011 resulting in the highest CPUE for over 30 years (Pearl Figure 3; Pearl Figure 4), but CPUE has now returned to normal levels as a result of spat settlements returning to normal levels.

Using the catch rate prediction system, the culture catch quota for 2015 was maintained at a unit value of 1,100 shells (TAC = 502,700) which is the same as 2014 (Pearl Figure 4). A small increase in CPUE is predicted for the following two years, 2016 and 2017. Fishers were also given an MOP...
quota of 240 shell per unit to further explore the potential of the MOP fishery, resulting in a total quota of 109,680 shells per unit.

**Zone 1:** The Zone 1 fishery was fished for the first time since 2008. Since then, the Zone 1 fishery has been in a state of rebuilding, particularly in the middle sector after some heavy fishing years in the mid-1990s to early 2000s. In 2008, the Zone 1 CPUE was 25 shells per hour, which was a slight increase from the 2007 CPUE of 23 shells per hour. In 2014 all culture shell were fished from one grid in the northern sector (Turtle Island) with a CPUE of 47 shells per hour, indicating 100% increase in the 2008 catch rate, albeit nominal fishing in only one grid. In 2014, MOP was fished from 2 grids in the northern sector (Turtle Island) with a CPUE of 70 shell per diver hour. With a significant change in the culture CPUE, it could indicate that a substantial recovery has taken place and further fishing activity in the years ahead.

**Breeding stock:** Under average growth and mortality and recent levels of TAC, recruitment into the pearl oyster breeding stock exceeds natural mortality, and hence breeding stocks are likely to be increasing in most years. This results from the ‘gauntlet’ fishing strategy employed by the industry, in which the young, fast-growing shell (principally males) of 100 – 165 mm shell length are targeted for their fast pearl-producing qualities. Despite the fishery trialling a minimum size of 100 mm for 3 years, the basis for quota setting remains the abundance within the 120-165 mm size class. Animals that survive this ‘gauntlet’ are effectively protected from the age of 6 to 7 years onward, and could have lived for another 15 to 20 years. With very low natural mortalities, this results in a large broodstock being built-up over time. The fishery is trialling the capture of a conservative level of MOP shell which should not make a significant impact on the breeding stock. In Zone 1, breeding stock should also be increasing due to the low effort since 2002, including no fishing in 2004, 2009 – 2013.

**Non-Retained Species**

**Bycatch species impact:** 

Divers have the ability to target pearl oysters of choice (species, sizes and quality of *P. maxima*). Pearl oysters brought to the vessel after hand collection are young and have relatively little epiphytic growth ( fouling organisms). A small number of over-sized or under-sized oysters are returned to the substrate.

The performance measures for this fishery, which relate to breeding stock biomass, include the area of fishing compared to the distribution of the stock and the catch rates of young oysters within each of the fishing zones.

All performance measures were met for 2014. The area of fishing remains substantially less than 60% of the distribution of oysters within this region. The catch rate in Zone 2 was above performance levels, with a catch rate of 38 oysters/hour. No culture shell were caught in Zone 3.

**Ecosystem Effects**

**Food chain effects:** 

The fishery removes only a small proportion of the biomass of pearl oysters on the fishing grounds and is considered to have negligible impact on the food chain in the fishing area.

**Habitat effects:** 

Pearl divers have minimal contact with the habitat during fishing operations. The main habitat contact is by pearl oysters held in mesh panels on holding sites following capture. However, these sites cover a very small proportion of the habitat and the activity concerned is unlikely to cause any lasting effect.

Similarly, the pearl farming operation, which uses longline systems in areas of high tidal flow to culture pearls, has limited impact on the environment. Physical effects are limited to static anchoring systems in typically sand/mud habitats. Environmental management research has demonstrated that pearl farming has negligible impacts on habitat and environment.

**Social Effects**

**Direct**

Pearl oyster fishing vessels operate from the Lacepede Islands north of Broome to Exmouth Gulf in the south. The number of vessels in the fishing fleet has been slowly reducing from 16 in 1997 (overall), mostly due to increased fleet efficiency and increased reliance on hatchery-produced shells. In 2009, with the negative impact of the Global Financial Crisis (GFC) on the industry, only two vessels fished. The number of vessels fishing in 2014 was six.

Most vessels presently operate 10 – 14 crew for the fishing of pearl oysters between March and August each year. These vessels also support shell operations and a number of other pearl farm functions throughout the year.

**Indirect**

Prior to the GFC, the pearling industry provided employment for approximately 500 people in the northern coastal regions, including in the operation of the pearl farms. However the impact of the GFC resulted in a substantial reduction in personnel employed in the pearling industry.

**Economic Effects**

**Estimated Total Industry value for 2014:**

- **Level 5 - > $20 million ($67 million)**

A precise estimate of the total industry value is difficult to achieve, owing to the variable time lags that occur between harvesting and sale to offshore buyers, and the costs incurred in marketing before sales take place. Based on information provided by the industry, the value of cultured pearls and by products in 2014 was considered to be approximately $67
million, which is 10% higher than 2013, in which it was $61 million.

Fishery Governance

**Target effort range:** 14,071 - 20,551 hours

**Target SCPUE range (Zone 2/3 fishery):**

25 - 90 shells per hour

The target effort range relates to the time required to achieve the TAC (culture shell only) in all zones of the pearl oyster fishery. Acceptable effort ranges for individual management zones are 11,456 – 15,819 dive hours for Zone 2/3 and 2,615 – 4,732 dive hours for Zone 1. These ranges are based on the 5-year period (1994 – 1998) following the introduction of global positioning systems (GPS) into the fishery, and reflect the typical variation in abundance of the stock under natural environmental conditions.

Historically, the target effort range has been the main governance / performance measure, however recent changes in the fishery such as the new management initiatives from the MSC assessment process has resulted in the development of new, more relevant indices for management. In 2013, a target SCPUE range was developed based on the 11 year time period 2003 – 2013 considered to reflect the typical variation in abundance of the stock under natural environmental conditions. This replaces the old target effort range, which has been provided for comparison.

Zone 2/3 of the pearl oyster fishery achieved its catch with 12,479 dive hours of effort, which was within acceptable effort range.

Zone 2/3 of the pearl oyster fishery achieved its catch at an SCPUE of 28 shells per hour, which was within the target range of SCPUE.

**Current effort level:** Acceptable

Overall fishery effort level is acceptable.

New management initiatives (2015)

The Department has approved the continuation of a trial for industry to take smaller shell legally, 100 - 119 mm until the end of 2016. The request to take smaller shell was put forward by industry to evaluate the economics for their business model. The Department has advised that there are no sustainability issues under a fixed TAC.

The pre-assessment phase for Marine Stewardship Council (MSC) approval was completed for the Pearl Oyster Fishery in 2014, with the Fishery to undergo full assessment during 2015.

A new State Act of Parliament to ensure the sustainability and management of all WA’s aquatic biological resources has been introduced into Parliament in 2015. The new Act (currently the Aquatic Resource Management Bill 2015) will replace both the Fish Resources Management 1994 and the Pearling Act 1990. The Department is facilitating a review of the current legislative framework ahead of the introduction of the new Act to adopt a more streamlined governance structure for the pearl oyster fishery and activities associated with pearl culture.

External Factors

The pearl oyster stocks underpinning the fishery in Zone 2/3 continue to provide a sufficient level of production to support this major Western Australian industry, however preliminary research points to environmental factors being an external driver of the spat settlement in 2005 and high abundance in the fishery in 2008-2011. A risk assessment on the vulnerability of species to climate change ranked pearl oysters as medium-high due to its sensitivity to water temperature and cyclones.

The industry will continue to experience difficulty from the Global Financial Crisis, which had a major impact on the market for luxury goods, including pearls. Future signs for 2015 suggest a market recovery and a stabilising of oyster abundance due to lower settlement. Finally, the on-going issue of the OOD (oyster oedema disease) continues to hamper hatchery-production capacity in some sectors of the Industry, however to date there is no evidence the disease has affected wild stocks.
PEARL FIGURE 1
Distribution of pearl oyster stocks and fishing zones in Western Australia.

PEARL FIGURE 2
Pearl shell catch and effort – Broome area (Zone 2/3). ‘Culture shells’ are pearl oysters ≥100 and <175 mm shell length, ‘MOP shells’ are oysters ≥175 mm

PEARL FIGURE 3
Standardized (SCPUE) and nominal (raw CPUE) pearl culture shell catch per unit effort in the Zone 2/3 fishery with threshold and limit reference points and target range indicated.
Harvest control rule for the culture shell in Zone 2/3 pearl oyster fishery. The current rule takes the form, TAC (2015) = 13.7*SCPUE2015 + 85.35; \( r^2 = 0.88 \). The harvest rule is updated with each annual assessment and prediction of future SCPUE.

Fishery Description

Beche-de-mer, also known as sea cucumbers or trepang, are in the Phylum Echinodermata, Class Holothuroidea. They are soft-bodied, elongated animals that usually live with their ventral surface in contact with the benthic substrate or buried in the substrate.

The Western Australian beche-de-mer fishery is primarily based in the northern half of the State, from Exmouth Gulf to the Northern Territory border, however fishers do have access to all Western Australian waters not specifically closed to fishing. It is a hand-harvest fishery, with animals caught principally by diving, and a smaller amount by wading. While six species have been taken, prior to 2007 it was primarily a single species fishery, with 99% of the catch being sandfish (Holothuria scabra). An additional species (deepwater redfish - Actinopyga echinites) was also targeted during 2007-2010 and 2014.

Governing legislation/fishing authority

Fisheries Notice no. 366
Exemption under Section 7(3)(c) of the Fish Resources Management Act 1994
Commonwealth Government Environment Protection and Biodiversity Conservation Act 1999 (Wildlife Trade Operation)
Consultation process

Industry Annual Management Meetings are convened by the Western Australian Fishing Industry Council (WAFIC), under a Service Level Agreement with the Department. Annual Broome Consultative Forum.

Boundaries

The beche-de-mer fishery is permitted to operate throughout Western Australian waters with the exception of a number of specific closures around the Dampier Archipelago, Cape Keraudren, Cape Preston and Cape Lambert, the Rowley Shoals and the Abrolhos Islands.

Management arrangements

The developing fishery for beche-de-mer is managed through input controls including limited entry, maximum number of divers, species-dependent minimum target size limits, and gear restrictions. Access to the fishery is limited to the 6 Fishing Boat Licence holders listed in the Instrument of Exemption enabling the take beche-de-mer.

Beche-de-mer may only be harvested by hand or diving by licensed commercial fishers operating under the authority of a Fishing Boat Licence that is listed on the Instrument of Exemption.

The maximum number of divers (per endorsed fishing boat licence) allowed to dive for beche-de-mer at any one time is four, with a maximum number of ten crew allowed on the vessel.

There are six species of beche-de-mer harvested in Western Australia. At present, the minimum target lengths for these commercial beche-de-mer species are based on the Northern Territory’s minimum sizes, which have been set based on size at sexual maturity.

A comprehensive Ecologically Sustainable Development assessment of this fishery has been undertaken to identify any potential sustainability risks requiring direct management. The only issue identified through this process related to the listed species interaction was negligible.

Research summary

Current research is focused on reporting of annual catch and effort statistics. A daily catch and effort logbook designed for the fishery was implemented in 2007. The logbook obtains species-specific, fine-scale catch and effort data and appropriate environmental information, such as depth fished. A population biomass survey is planned for the A. echinites stock in 2015.

Retained Species

Commercial landings (season 2014)

93 tonnes (live weight)

Landings

Industry has advised they are adopting a rotational fishing strategy for both the traditional sandfish Holothuria scabra fishery and recently discovered A. echinites fishery. Fishing activity within the Western Australian fisheries was in a resting phase during 2013. In 2014 fishing recommenced with a catch of 48 t of Actinopterygii echinites, 40 t of Holothuria scabra, 4.7 t of Holothuria whitmaei and 0.5 t of other species being A. lecanora (Stonefish), A. milaris (Blackfish), and Stichopus herrmanni (Curryfish). Current trends of catch and effort within the fisheries are shown in Beche-de-mer Figure 1a and Table 1.

Fishing effort/access level

Two of 6 licensed vessels fished for beche-de-mer in 2014, with 1000 dive hours fishing. From this total, 54 dive hours comprised of exploratory fishing further south into the Gascoyne region targeting other species.

Stock Assessment

Assessment complete: Yes
Assessment level and method: Level 2 - Catch rate
Breeding stock levels: Adequate

Estimates of Maximum Sustainable Yield (MSY) of sandfish were obtained for the entire WA fishery and Kimberley sub-regions using a biomass dynamics model. Current average catch of sandfish is below the MSY (Beche-de-mer Table 2), indicating that the level of fishing is sustainable. However, large variability in the estimates of q (0.21 – 0.55) for the same species suggests that a cautious interpretation of the model outputs is required. The model is updated with new data every year.

The species performance measure for the Sandfish fishery are catches remaining in the range 20 – 100 t and catch rate remaining above 25 kg/hour. In 2014, catch and catch rates satisfy the performance measures (Beche-de-mer Figure 1b).

The species performance measure for the Redfish fishery are catches remaining in the range 40 – 150 t and catch rate remaining above 60 kg/hour. In 2014, catch and catch rates satisfy the performance measures (Beche-de-mer Figure 1b).

Non-Retained Species

Bycatch species impact: Negligible

No bycatch species are known to be taken in this fishery. Given the selective method of fishing used (diving or wading, collection by hand only), the minimal level of interaction with other species is likely to be maintained.

Listed species interaction: Negligible

There are currently no known interactions with listed species in this fishery and given the methods of collection this is likely to remain the case.
Ecosystem Effects

Food chain effects: Negligible

This fishery harvests only a small amount of sandfish and redfish per annum. The effect from this harvesting on the rest of the ecosystem, given that the catch is spread over a wide region, would be insignificant.

In addition, predation on beche-de-mer is relatively infrequent due to the toxins present in their body tissues. It is highly unlikely these animals are a major diet for higher-order predators, due to these toxins acting as an effective defence system.

Habitat effects: Negligible

Divers collect beche-de-mer as they drift over the bottom; there is minimal impact on the habitat as divers are highly selective in their fishing effort and no fishing gear or lines contact the seabed. The vessels work during the day and anchor at night, usually further inshore where they are protected from the open ocean that is subject to higher seas and wind. Most fishers are mindful of the habitat they choose to anchor over, so they avoid more diverse bottom habitat.

There are some areas where fishers can access beche-de-mer by wading through shallow water mangrove lagoons and estuaries. This is a minor component of the fishery. Wading usually occurs on soft sandy substrates, with minimal impact on these habitats.

Social Effects

Generally a vessel employs 4 to 6 crew with one of those a master, a deckhand and remaining divers. Additional individuals are employed for the processing of the product. These activities are mostly located in the Northern Territory where the fishing fleet is based.

Economic Effects

Estimated annual value (to fishers) for 2014:

Level 1 - < $1 million

The estimated annual value for 2014 was $280,500 based on an average product price of $3.00 per kg live weight and total catch of 93.5 tonnes. This is a farm-gate value and supports a substantial processing and value adding sector.

Fishery Governance

Sandfish catch range: 20 – 100 tonnes
Redfish catch range: 40 – 150 tonnes

New management initiatives (2014/15)

A review of the beche-de-mer fishery is planned for 2014/15. It is anticipated that this review will result in the fishery transitioning from Exemption based to interim managed during 2015/16.

The species-specific information on catch and effort from the daily logbook, implemented in 2007, has facilitated the development of species-specific performance indicators and these will be refined as more information arises.

External Factors

The remoteness of the currently fished stock and the large tidal ranges where it occurs are natural barriers to uncontrolled expansion of fishing. Marine park planning has to date restricted this fishery from general use zones of some MPAs. However consideration of removal of this restriction is currently underway as most other fisheries have access to general use zones. If successful, this action will likely see some expansion into previously unfished areas. Currently, lack of experienced fishers and suitable vessels is restricting catch to low levels. This situation is expected to change within the next two years as a result of the fishery transitioning to interim managed status.

Fishery Description

Blue Swimmer Crab
The blue swimmer crab (Portunus armatus) is found along the entire Western Australian (WA) coast, in a wide range of inshore and continental shelf areas, from the inter-tidal zone to at least 50 m in depth. However, the majority of the commercially and recreationally-fished stocks are concentrated in the coastal embayments and estuaries between Geographe Bay in the south-west and Port Hedland in the north.

Blue swimmer crabs are targeted using a variety of fishing gear but most commercial crab fishers in WA now use purpose-designed crab traps. Operators in the Pilbara Developmental Crab Fishery are only permitted to use ‘hourglass’ traps. The Onslow and Nickol Bay prawn trawl fisheries also retain crabs as a by-product.

The Pilbara Developmental Crab Fishery was established in 2001 via the Developmental New Fisheries process, following the granting of an exemption from existing trap prohibition legislation, pursuant to section 7 of the Fish Resources Management Act 1994 (FRMA). The exemptions were issued to allow for the sustainable exploration of the commercial viability of fishing crab stocks along the Pilbara coastline.

Mud Crab
Four species of mud crab (Scylla spp.) have been identified in the Indo-West Pacific region, of which the green mud crab (Scylla serrata) and brown mud crab (Scylla olivacea) occur in Western Australia (Keenan et al., 1998). The maximum size reported for green mud crabs is between 250 – 280 mm carapace width (CW) (Lloris, 2001), whereas the maximum size of brown mud crabs is between 135 – 139 mm CW (Tongdee, 2001). A species identification waterproof card outlining minimum legal size limits and defining characteristics between green and brown mud crabs was produced by the Department of Fisheries in 2011 and is widely available to members of the public.

The green mud crab is predominantly found in estuarine habitats in north-western Australia from the Northern Territory border to Shark Bay, but have also been found as far south as the Wilson Inlet at Denmark in years of strong southern coastal Leeuwin Current flow (Gopurenko et al., 2003). The brown mud crab has a more restricted distribution limited to northern embayments, with most catches from King Sound 200 km northwest of Broome.

Brown mud crabs are more tolerant of low salinity than green mud crabs, but less tolerant of lower temperatures. They are also considered to exhibit a strong preference for the intertidal zone, while green mud crabs make regular use of both intertidal and subtidal habitats up to 20 m depth offshore (Hill, 1994; Robertson, 1996).

The Kimberley Developing Mud Crab Fishery is currently a small developing fishery that targets the green mud crab and the brown mud crab via the use of crab traps, between Broome and Cambridge Gulf near the WA and Northern Territory border, with fishing effort concentrated around Cambridge Gulf, Admiralty Gulf, York Sound and King Sound (see North Coast Crab Figure 1 and 2). From 1994 to 2005 commercial fishing for mud crabs was authorised through permissive conditions on Fishing Boat Licences. From 2006 to present, access to the Kimberley Developing Mud Crab Fishery has been granted via Exemptions, which were formerly issued under Section 7(3)(c) of the Fish Resources Management Act 1994, for ‘the exploration or development of fisheries or the development of fishing technology’.

The design of mud crab trap permitted to be used is not prescribed in the management arrangements at present, in order to allow some flexibility for exemption holders to determine the most appropriate gear for the high tidal conditions. However, prior to using the trap, the design of mud crab traps must be approved by the Department of Fisheries. At present in the Fishery there are two styles of mud crab trap used, a rectangular trap and a round trap. The rectangular design generally follows the dimensions of not more than 1000 mm length, 600 mm width and 300 mm height with a rigid mesh of 50x70 mm with 2 openings for crabs to enter the trap. The round trap design is generally 500 mm high; 1000 mm diameter with flexible nylon mesh of around 50 mm mesh size (knot to knot) with 4 openings for crabs to enter the trap.

Access to the Kimberley Developing Mud Crab Fishery is made up of two broad groups: Aboriginal Community Commercial Mud Crab Exemption holders and Commercial Exemption holders. There are currently 3 commercial operators and 2 Aboriginal corporations holding exemptions to fish for mud crabs in WA. The fishers generally operate from March to November, with May to September being the most productive months, to avoid summer and associated seasonal cyclone weather events. Commercial operators generally fish on a part-time basis with most operating other endorsements including Kimberley Gillnet and Barramundi Managed Fishery Licences and fishing boat charters. Operators tend to fish remote waters for long periods of time in large mother ships, using small dinghies known as dorys to enter mangrove estuaries with crab traps generally checked each daylight high tide.

Consultation process
Commercial
Industry Annual Management Meetings are convened by the West Australian Fishing Industry Council (WAFIC), under a Service Level Agreement with the Department. Annual Broome Consultative Forum (Mud crabs)

Recreational
Consultation processes are now facilitated by Recfishwest under a Service Level Agreement although the Department undertakes direct consultation with the community on specific issues.

Boundaries
Blue Swimmer Crab
Crabbing activity along the Pilbara coast is centred largely on the inshore waters from Onslow through to Port Hedland, with most commercial and recreational activity occurring in and around Nickol Bay.

The boundaries of the Onslow Prawn and Nickol Bay Prawn Managed Fisheries which also capture crabs as by-product are described in the relevant status report elsewhere within this document.

Mud Crab
Three commercial operators are permitted to fish from King Sound to the Northern Territory border, with closed areas around communities and fishing camps. One Aboriginal Corporation is permitted to fish in King Sound, with the other Aboriginal Corporation permitted to fish in a small area on the western side of the Dampier Peninsular, north of Broome.

Notices issued under the Fish Resources Management Act 1994 prohibit all commercial fishing for mud crabs in Roebuck Bay and an area of King Sound near Derby.

Management Arrangements
Blue Swimmer Crab
Commercial access to blue swimmer crab stocks in WA is governed by a series of separate management arrangements provided for under the legislative framework of the Fish Resources Management Act 1994. Individual fisheries are managed under an input control system, primarily through the regulation of vessel and trap numbers. Supplementary controls cover retainable species and associated minimum size limits, gear specifications, and spatial, seasonal and daily time restrictions. The principal management tool employed to ensure adequate breeding stock in the commercial crab fisheries involves maintaining minimum size limits well above the size at sexual maturity. The commercial minimum size of 135 mm carapace width which applies in the Pilbara Developmental Crab Fishery should ensure adequate egg production for associated blue swimmer crab stocks under typical environmental conditions.

The management arrangements for the Pilbara Developmental Crab Fishery are set by conditions on the exemption and are aimed at ensuring the stock and environment are protected. A maximum of 400 crab traps is permitted in the fishery.

Management controls for the Onslow and Nickol Bay Prawn Managed Fisheries are based on limited entry, seasonal and spatial closures, moon closures, and gear controls including bycatch reduction devices (grids). The fleet is composed of trawlers up to 23 metres in length; operating twin- or quad-rigged otter trawls to a maximum head-rope length of 20 fathoms (36.6 m). The Department of Fisheries’ Vessel Monitoring System (VMS) monitors the activities of all trawlers in these fleets.

Recreational fishing for blue swimmer crabs in WA is managed through a series of input and output controls. As with commercial fishing, the principal management tool employed to sustain an adequate breeding stock involves maintaining minimum size limits well above the size at sexual maturity. A minimum legal size limit of 127 mm carapace width applies in the waters of the North Coast Bioregion, along with a bag limit of 20 crabs per person with a boat limit of 40 crabs. Restrictions also govern gear types that can be used to take blue swimmer crabs (drop nets, scoop nets only).

Mud Crab
Since 2006, access to the Kimberley Developing Mud Crab Fishery has been granted via Instruments of Exemption, issued under Section 7 of the Fish Resources Management Act 1994. The mud crab fishery is managed under an input control system, primarily through the regulation of vessel and trap numbers (maximum of 1,070 traps), gear restrictions and spatial closures. Three commercial operators are permitted to fish 300 traps from King Sound to the Northern Territory border, one Aboriginal Corporation is permitted to fish in King Sound using 150 traps, with the other Aboriginal Corporation permitted to fish in a small area on the western side of the Dampier Peninsular, north of Broome using 20 traps. Prior to the exemption not being renewed in 2011, a third aboriginal corporation fished in Carnot Bay and Camp Inlet using 20 traps.

From 1 May 2013, mud crab exemption holders were permitted to retain bycatch of other Portunid crabs for a two year trial period which ended on 30 April 2015. Negligible catches of blue swimmer crabs were retained during this trial. A minimum size limit of 135 mm for blue swimmer crabs was imposed, consistent with the size limit used in the Pilbara Developmental Crab Fishery. No limits were placed on the number of blue swimmer crabs retained.

Breeding stocks are protected by maintaining minimum size limits (150 mm CW for green mud crab and 120 mm CW for brown mud crabs) set well above the size at sexual maturity (90-120 mm CW for green and 86-96 mm CW for brown). This was later revised to 131-138 mm CW for green mud crabs.
crabs after reclassification of the Scylla genus (Knuckey, 1999). These size limits apply to both the commercial and recreational take of the species.

Recreational fishers for mud crabs are restricted to a daily bag limit of 5 mud crabs, with a boat limit of 10 mud crabs.

Research Summary
Blue Swimmer Crab
Data for the assessment of blue swimmer crab stocks in the North Coast Bioregion is obtained from trap fishers’ compulsory monthly catch and effort returns and daily research logbooks. Baseline information on the biology and ecology of blue swimmer crabs has been generated by a number of Fisheries Research and Development Corporation (FRDC)-funded projects conducted by the Department of Fisheries and Murdoch University over the past decade.

Mud Crab
Data for the assessment of mud crab stocks in the North Coast Bioregion is obtained from trap fishers’ compulsory monthly catch and effort returns and daily research logbooks. Relevant research information is sourced from 2 recent FRDC funded projects involving NT Fisheries investigating escape gap sizes of traps (Grubert & Lee., 2012) and environmental correlations with mud crab catches in the Northern Territory (Meynecke et al., 2010). A third FRDC project has also been recently completed on equipping the mud crab industry with innovative skills through extension of best practice handling (Poole et al., 2012).

Retained Species
Commercial landings (season 2013/14):

<tr>
<td>Mud crabs</td>
<td>12.9 tonnes</td>
</tr>
</tbody>
</table>

Blue Swimmer Crabs
The combined commercial catch of blue swimmer crabs from trap-based crab fishers and prawn trawlers operating along the Pilbara coast during 2013/14 was 45.9 t, a 62% increase on the 2012/13 catch of 5.8 t and the highest catch since 2006/07 (North Coast Crab Figure 3). The majority of the 45.9 t recorded catch was taken by the trap fishery, with trawlers retaining only 4.7 t of crab during 2013/14. This Pilbara catch accounted for 8% of the state commercial blue swimmer crab catch of 552 t for 2013/14 (West Coast Blue Swimmer Crab Figure 1).

Mud Crab
The total trap catch of mud crab for the Kimberley Developing Mud Crab Fishery during 2014 was 12.9 t (North Coast Crab Figure 5). An additional 3 kg was reported from Swan-Canning Estuary. This catch represents a 63% increase on the 7.9 t reported in 2013 and is the highest catch on record; 39% higher than 2006 when the developmental fishery commenced. In 2014 the majority of catch was recorded as green mud crab, while a small proportion was recorded as brown mud crab.

During the 2014 fishing season, mud crab exemption holders were permitted to retain Portunid crabs as part of an experimental trial. A total of 263 kg of blue swimmer crabs were landed from Cambridge Gulf with the majority being caught between September and December by one commercial operator.

Recreational catch:
Blue Swimmer Crab (boat-based) (May 13 – Apr 14) 4.2 tonnes

A statewide survey of boat-based recreational fishing was conducted between 1st May 2013 and 30th April 2014 and was a collaboration between the Department of Fisheries, Edith Cowan University and RecFishWest. Approximately 3,000 fishers from the “Recreational Fishing from Boat” licence database participated in a 12 month phone-diary survey in conjunction with boat ramp surveys of boat-based fishers. Catch data were recorded in numbers of crabs, and have been converted to weight for this report using a mean statewide estimate of 254 g/crab (based on 346 crabs weighed during the boat ramp surveys). The survey provided a statewide boat-based recreational estimate of retained blue swimmer crabs for the 12-month period of 72 t (S.E.=±4.8 t) (Ryan et al., 2015). The boat-based catch estimate for the North Coast Bioregion was 4.2 t (S.E.=±0.9 t), representing approximately 6% of the state’s recreational catch.

Mud Crab
The statewide survey of boat-based recreational fishing was also used to estimate the mud crab catch. Catch data were recorded in numbers of mud crabs, and have been converted to weight for this report using a mean statewide estimate of 649 g/crab (based on 72 mud crabs weighed during the boat ramp surveys). The survey provided a statewide boat-based recreational estimate of retained mud crabs for the 12-month period of 7.3 t (S.E.=±0.98 t) (Ryan et al., 2015). The boat-based catch estimate for the North Coast Bioregion was 5.9 t (S.E.=±0.89 t), representing approximately 81% of the state’s recreational catch. Of the 5.9 t caught in the North Coast Bioregion, 3.5 t (60%) was caught in the Kimberly and 2.4 t (40%) was caught in the Pilbara.

Fishing effort/access level
Blue Swimmer Crab
Crab trap fishers along the Pilbara coast reported 23, 025 trawlflits during 2013/14, which is a 184% increase on the 8,100 trawlflits reported for 2012/13 (North Coast Crab Figure 4).

---

Mud Crab
Mud crab fishers along the Kimberley coast reported 21,699 traplifts during 2014, a 136% increase on the 9,190 traplifts reported for 2013 (North Coast Crab Figure 5). There were two commercial fishers operating between April and August 2014, however this increased level of effort is likely due to extensive and prolonged exploratory fishing effort by 1 commercial fisher in the latter part of 2014.

Stock Assessment
Assessment complete:
Blue Swimmer Crab Pilbara - Yes
Mud Crab Kimberley - Yes
Assessment level and method:
Blue Swimmer Crab Level 2 - Catch rate
Mud Crab Level 2 - Catch rate
Breeding stock levels:
Blue Swimmer Crab Pilbara - Adequate
Mud Crab Kimberley- Adequate

Blue Swimmer Crab
The development of appropriate mesh sizes for use on commercial crab traps has eliminated the catch of juvenile crabs (< 80 mm carapace width) and significantly reduced the catch of undersize crabs < 120 mm carapace width, without impacting on legal catches. Improved work practices have also reduced the mortality of returned undersize and berried crabs caught in commercial traps to negligible levels.

The minimum legal size (127 mm carapace width for recreational fishers; 135 mm carapace width for commercial fishers) for crab fisheries in the North Coast Bioregion is set well above the size at first maturity of the resident stocks (based on size at maturity of crabs in Shark Bay - 97 mm CW males and 92.4 mm CW females, de Lestang et al., 2003). Consequently, breeding stock levels are expected to be adequate to maintain stocks in all current fishing areas under normal environmental conditions. The breeding stocks along the Pilbara coast are also supported by the influence of the warmer waters that occur at these latitudes which extends the spawning period over the whole year, whereas spawning is restricted to the late spring and early summer months on the lower West Coast. However, while warm temperatures during the winter have been shown to positively influence the recruitment in Shark Bay, extreme warm summer temperatures have been shown to have a negative effect.

Catch rates from the Pilbara trap fishery provides an index of abundance that can be used to assess fishery performance from year-to-year. Blue swimmer crab trap catch rates in the Pilbara Developmental Crab Fishery increased steadily during the first three years of exploratory fishing for blue swimmer crabs along the Pilbara coast. This reflected more efficient fishing of stocks in the Pilbara region, as the commercial operators’ knowledge of the spatial distribution of resident stocks and localized environmental influences increased over time. The increase in catch rate can also be attributed to improvements to fishing gear and vessels. Favourable environmental conditions led to a significant increase in catch rates (1.6-1.8 kg/traplift) from 2004/05 to 2006/07, before returning to longer-term mean catch rates (0.7-1.0 kg/traplift) between 2007/08 and 2012/13.

The Pilbara Developmental Crab Fishery recorded a mean catch rate for 2013/14 of 1.8 kg/trap lift – the highest recorded catch rate and a 156% increase on the catch rate of 0.7 kg/traplift reported during the previous year (North Coast Crab Figure 4).

A preliminary harvest strategy has been determined for this fishery where the primary performance indicator is nominal annual catch rate for the Nickol Bay Region (CAES blocks 2016, 2017), as the majority of fishing has been focused in this area historically. The reference period is between 2005 and 2011 as defined by the commencement of the developing fishery in 2005. As there is no season for this fishery the harvest strategy is based on calendar year. The nominal catch rate of 1.8 kg/traplift for the 2014 calendar year was well above the threshold of 0.6 kg/traplift, so currently the risk to sustainability is low.

Mud Crab
The minimum legal size at first capture is 150 mm carapace width (CW) for green mud crab (Scylla serrata) and 120 mm CW for brown mud crab (Scylla olivacea). This is set well above the size at first maturity of 90-120mm CW for green and 86-96mm CW for brown mud crab fisheries in the North Coast Bioregion (Knuckey, 1999). Consequently, breeding stock levels are expected to be adequate to maintain stocks in all current fishing areas under normal environmental conditions.

Between 1994 and 2005, trap catch and effort for mud crabs in the Kimberley remained low, ranging between 68 kg and 2.9 t and between 40 traplifts and 5,250 traplifts. Catch rate varied significantly during these years between 0.2 and 2.0 kg/traplift. When exemptions were formally established for commercial fishers and Aboriginal corporations in 2006, the catch and effort peaked at 9.3 t from 18,720 traplifts. The majority of catch and effort was attributed to the extensive exploratory efforts of a single fisher with catch per unit effort for the fishery around 0.5 kg/traplift. Although catch and effort declined in 2007, catch rate increased to 1.1 kg/traplift potentially due to greater knowledge of the fishery. Catch and effort remained fairly stable in 2008 and 2009 (~ 5 t from ~8,000 traplifts) but then declined due to a lack of fishing by the majority of fishers, with one exemption not renewed in 2011. Catch rate over the past 5 years (2010 – 2014) has fluctuated between 0.5 and 0.9 kg/traplift, with a catch rate of 0.6 kg/traplift reported in 2014. Historically, the majority of commercial crabbing has occurred in the areas of Cambridge Gulf, Admiralty Gulf, York Sound and King Sound. During 2014, fishing was reported from Collier Bay and York Sound and the majority of catch was recorded from Cambridge Gulf.

A preliminary harvest strategy has been determined for The Kimberley Developing Mud Crab Fishery where the primary performance indicator is nominal annual catch rate. The reference period is between 2006 and 2011 as defined by the commencement of the developing fishery in 2006. As there is no season for this fishery the harvest strategy is based on calendar year. The nominal catch rate of 0.6 kg /traplift for the 2014 calendar year declined from last year as a result of the increased effort but remained above the threshold of 0.5 kg/traplift.
kg/traplift, so currently the risk to sustainability is low. However, due to the catch rates proximity to the threshold it will be monitored closely in 2015 to ensure that it does not fall below the threshold.

Non-Retained Species

**Bycatch species impact**  Negligible

**Blue Swimmer Crab**
The shift from using gillnets to traps in most blue swimmer crab fisheries has resulted in a substantial reduction in bycatch from dedicated crab fishing. Pots are purpose-designed to minimise the capture of non-target species and are therefore an inefficient way to capture fish, the majority of which are able to escape through the entrance gaps when the pot is soaking or being hauled.

Small numbers of fish are infrequently captured in crab pots, but the fishers are not permitted to retain them. The low number of fish caught and returned by crab fishers is considered to pose a negligible risk to these stocks.

Discarded bycatch from trawl fisheries that retain crabs as a by-product is dealt with in those sections of this report specific to the trawl fisheries.

**Mud Crab**
Mud crab traps are purpose built to effectively target larger (legal sized) mud crabs. The overall trap design and large mesh size allows sub legal mud crabs and non-targeted bycatch species opportunity to escape the trap, preventing them from being retained. The gear is required to be pulled regularly, and undersized and berried crabs must be returned to the water.

**Listed species interaction**  Negligible

**Blue Swimmer Crab**
The crab trap longline system used in the targeted crab fisheries has little possibility of interacting with listed species. The fishery is conducted in a manner that avoids mortality, or injuries to, endangered, threatened or protected species and avoids or minimises impacts on threatened ecological communities.

**Mud Crab**
As mud crab traps are purpose built to target mud crab species and are set for relatively short periods of time, the possibility of causing harm to listed species is minimal.

Ecosystem Effects

**Food chain effects**  Low

**Blue Swimmer Crab**
As the commercial take of crabs represents a relatively small portion of the biomass, which is effectively renewed annually, secondary food chain effects are likely to be minimal in these fisheries.

**Mud Crab**
As the retained commercial catch of mud crabs is low, the commercial fishery represents a small proportion of the available biomass. Therefore secondary chain effects would not be likely to be significant within the surrounding ecosystem of the fishery.

**Habitat effects**  Negligible

**Blue Swimmer Crab**
Fishing with traps results in limited habitat disturbance, with only minor dragging of traps on the sea bottom during trap retrieval. Sand and associated biota does not get brought to the surface in commercial blue swimmer crab traps, as the mesh used on traps is sufficiently large to allow the escape of any sand-dwelling macro-benthos.

Although seagrasses are occasionally uprooted and brought to the surface with the trap, the infrequent nature of this occurrence, and the small amount of living seagrass removed, results in minimal habitat damage.

**Mud Crab**
Trap fishing in the shallow waters of associated mangrove tidal creeks and near shore embayments results in limited habitat disturbance. The large mesh size prevents capture of benthic organisms and only minor dragging of traps on the sea floor occurring in trap retrieval. The sheltered shallow mangrove environment is protected from wind and waves where the majority of traps are deployed, resulting in minimal habitat damage.

Social Effects

**Blue Swimmer Crab**
During 2013/14, two people were employed as skippers and crew on vessels fishing for blue swimmer crabs along the Pilbara coast. Additional employment for several workers has been created in Point Samson through the development of post-harvest processing of the crab catch.

**Mud Crab**
Historically the mud crab fishery has had a high community value and a low commercial value. Commercial fishers travel vast distances due to the remoteness of their operations and stay in the vicinity for several weeks before returning to unload catch. In this scenario crabs are frozen and generally sold to local markets although live product may also be sold at premium prices.

There were two commercial operators that fished during 2014, with effort concentrated between April and August with one operator fishing through December.

Economic Effects

**Estimated annual value (to fishers)**  Level 1 - < $1 million

**Blue Swimmer Crab**
Average beach price for trap caught blue swimmer crabs across all Western Australian fisheries for 2013/14 was around $5.24/kg. Price data was generated by collecting monthly returns recording prices paid to fishers by fish processors, a weighted-average price is then calculated for the financial year from the monthly data collected. Based on this beach price, the total commercial blue swimmer crab catch in the North Coast Bioregion for 2013/14 was valued at approximately $240,754, a 306% increase on the $53,300
generated in 2012/13. Of this, $216,360 was reported from the
trap sector. The crab catch from the Pilbara region was sold
through local and interstate markets.

Based on the WA state beach price the economic value of the
total commercial blue swimmer crab catch for the State of
Western Australia for the 2013/14 financial year was
estimated to be $2.9 million – a 13% increase on the
estimated $2.6 million generated in 2012/13.

**Mud Crab**
The average beach price for green (uncooked) mud crabs in
the Kimberley for 2014 was around $23.61/kg (however note
this value is based on a small proportion of total catch from
an individual processor). Price data was generated by
collecting monthly returns recording prices paid to fishers by
fish processors, a weighted average price is then calculated
for the financial year from the monthly data collected.

Mud crab landings from the Kimberley mud crab fishery
during 2014 were worth approximately $303,908 a 74%
increase on the $174,572 generated in 2013. As the
Kimberley region is the only commercial mud crab fishery in
Western Australia this essentially represents the total value of
the commercial mud crab fishery in Western Australia.
Aboriginal corporations may also trade and barter product
adding value to the local communities that cannot be
estimated.

**Fishery Governance**

**Target catch (or effort) range:**

- **Blue Swimmer Crab Pilbara**: N/A
- **Mud Crab**: N/A

**Current fishing (or effort) level:**

- **Blue Swimmer Crab**: Pilbara - Acceptable
- **Mud Crab**: Acceptable

**Blue Swimmer Crab**
While the Pilbara Developmental Crab Fishery has
undergone a steady expansion since exploratory fishing for
blue swimmer crab stocks between Onslow and Port Hedland
began in 2001, effort levels in the fishery are considered
acceptable. The large area covered by the fishery and the
remote nature of much of this coastline provides significant
logistical and financial challenges in returning the harvested
catch to market in an acceptable time period. Improvements
to fishing gear and vessels, along with a substantial increase
in the understanding of local environmental influences such
as tide and wind, has allowed commercial fishers to improve
fishing practices with effort decreasing in recent years.
Fishing effort in this region is limited by very hot weather
experienced during the summer months, which generally
restricts fishing effort to between April and November.

**Mud Crab**
The mud crab fishery is currently being fished at
low/precautionary levels due to the low number of fishers
operating in the fishery and relatively low effort across a
large area of the Kimberley. Although some fishing occurs in
localised areas of the coastline it is believed that stock levels
are not being significantly affected at this time.

**New management initiatives (2014/15)**

**Blue Swimmer Crab**
The Department is currently progressing formal management
arrangements of the Pilbara Crab DNF through the
development of a (Interim) Management Plan for the fishery.
This is scheduled to be completed in 2015.

**Mud Crab**
The Department proposes to bring the Kimberley Developing
Mud Crab Fishery under formal management arrangements in
2015.

**External Factors**
Levels of recruitment to many of the crab fisheries fluctuate
considerably. While the causes of these variations are not
fully understood, it is considered most likely due to
environmental influences on spawning success and larval
survival through to recruitment. The relationship between
environmental factors, recruitment and catch is being further
evaluated as data becomes available. Blue swimmer crabs
were rated a high risk to climate change due to their
sensitivity to water temperature changes.
NORTH COAST CRAB FIGURE 1
Areas fished for mud crab along the Kimberley coast of Western Australia.

NORTH COAST CRAB FIGURE 2
Key areas fished by exemption holders operating in the Kimberley Developing Mud Crab Fishery in Western Australia.

NORTH COAST CRAB FIGURE 3
Total commercial catch history for the blue swimmer crab (*Portunus armatus*) along the Pilbara coast since 2000/01. Data represents the total crab catch for trap and trawl sectors and effort in fisher days.
**NORTH COAST CRAB FIGURE 4**

Commercial trap catch history for the Pilbara Developmental Blue Swimmer Crab (*Portunus armatus*) fishery since 2000/01. Data represents the total trap crab catch (t), effort (traplifts x 1000) and catch per unit effort (CPUE) (kg/traplift).

**NORTH COAST CRAB FIGURE 5**

Annual catch (t), effort (traplifts x 1000) and catch per unit effort (CPUE) (kg/traplift) for mud crab in the Kimberley Region since 1994 when permissive conditions of fishing boat licences were issued. The Kimberley Developing Mud Crab fishery commenced by exemption in 2006.

**AQUACULTURE**

Regional Research and Development Overview

Aquaculture in the North Coast Bioregion is dominated by the production of South Sea pearls from the silver lip pearl oyster *Pinctada maxima*. This industry sector utilises both wild-caught and hatchery-reared oysters to produce cultured pearls. The wild-stock fishery is reported in the North Coast Bioregion section of this volume.

The Department of Fisheries also has a major role in the management and regulation of pearl hatcheries, seeding activities and pearl oyster farm leases.

A Memorandum of Understanding between the Western Australian and Northern Territory fisheries ministers, signed in June 2006, recognises that WA and the NT comprise the entire Australian south-sea pearling industry and that product from both jurisdictions supplies the same market.

To assist in addressing the regulatory and approvals issues concerning aquaculture development in WA, the Department of Fisheries has received Government funding of $1.85 million to establish two aquaculture zones in the Kimberley and Mid-West regions. Through this project, the Department of Fisheries will secure strategic environmental approvals for the zones, thereby streamlining the approvals processes for commercial projects within zoned areas and providing an “investment ready” platform for prospective investors.
The North Coast bioregion extends from the Ashburton River near Onslow to the Northern Territory border. The bioregion is both expansive and diverse, covering over 2600km and containing a huge range of fish that are targeted by commercial and recreational fishers. Tourism is a major part of the coastal towns in the North Coast with over 600,000 additional people visiting the area each year. The transient population increases in the cooler months from May to October including international, interstate and intrastate tourists.

Many of the towns in this bioregion support mining communities where fly in / fly out is common. Surveys have shown that a large proportion of mining community and tourists take part in fishing while visiting the bioregion.

Within the North Coast Region, creek systems, mangroves, rivers, offshore islands, coral reef systems and continental shelf waters provide for a wide range of shore and boat fishing opportunities.

Three district offices located in Kununurra, Broome and Karratha provide compliance and education across the region with fifteen permanent Fisheries and Marine Officers and one Community Education Officer. An additional two officer Recreational Mobile Patrol operates throughout the North Coast Region. Compliance is delivered to several sectors including commercial and recreational fisheries, pearling, aquaculture, fish habitat and bio-security.

The North Coast Region is sparsely populated in most areas with much of the terrain remote and difficult to access. Remote patrols are undertaken for up to two weeks at a time to get to these areas. Specialised equipment is required for patrols including four wheel drive vehicles and a variety of vessels for inshore coastal and inland waters, when offshore patrols are conducted, a 23 metre patrol vessel is utilised. A range of compliance duties are carried out in the bioregion including investigations, catch, licence, gear, processor, retail and transport inspections. These are carried out through roadside checks, land & sea patrols and aerial surveillance.

The Community Education Officer develops programs and coordinates the delivery of educational activities to a range of targeted audiences. They reach a wide range of people including school aged children and retirees, who come north to escape the cold and throw a line.

FMO’s also support community education where possible by supporting the Community Education Officer at a variety community events and fishing competitions.

**Activities during 2013/14**

Compliance delivery in the North Coast region requires careful planning due to the vast expanse of coastline, huge tidal variations, the variety of commercial and recreational fisheries and seasonal weather conditions which can often see road closures and flash flooding during the wet.

Fisheries and Marine Officers delivered a total of 7,811 officer hours of active compliance patrol time during 2013/14. FMOs also achieved 19,628 personal compliance contacts with fishers and non-fishers across the commercial and recreational sectors representing an increase on the previous year.

Officers made contact with a total of 203 commercial fishers in the field, across the north coast, again representing an increase on the previous year. This resulted in 18 infringement warnings, 16 infringement notices being issued and 37 matters resulting in prosecution action.

Compliance inspections were also carried out on Pearl oyster fishing and seeding operations, during transport of Pearl oysters and at various Pearl oyster lease sites. Considerable travel time is required to reach many of the lease sites, due to their remote locations.

Officers made contact with a total of 18,346 recreational fishers in the field, across the north coast.

From this sector 211 infringement warnings and 233 infringement notices were issued and 15 matters resulted in prosecution action.

Education activities for the 2013/14 period included the delivery of school incursions and excursions, school holiday programs, teacher professional learning sessions, community presentations and regional events such as fishing competitions and agricultural shows. A total of 4,655 contacts were recorded across the north coast region. When possible, education initiatives were delivered in partnership...
with key stakeholders such as; RecFishWest, Department of Parks and Wildlife and local fishing clubs.

**Initiatives in 2014/15**

Compliance and management staff continue to refine compliance planning to deliver greater outcomes. This has resulted in greater efficiency and ability to deploy resources more effectively.

The North Coast bioregions FMOs will continue to use a risk assessment based approach to fisheries compliance to ensure areas and activities of a high risk of non-compliance are targeted.

The Department will continue dedicated compliance and education patrols of the Camden Sound and 80 Mile Beach Marine Parks.

**At-sea compliance patrols of the 80 Mile Beach Marine Park** will continue utilising the Departments first amphibious vessel, purposely built to be launched and retrieved in the large tides encountered in the Kimberley.

The Northern Region Mobile Patrol, comprising of two FMOs will continue to focus entirely on recreational fisheries compliance and education throughout the Northern Region.

The education program for the north coast will focus on recreational fishers. While school based education is still a very important aspect of the program, the emphasis will decrease for 2014/15. By working more closely with FMO’s the program will aim to address some key compliance issues that occur in the region such as the use of illegal traps and species misidentification.

**NORTH COAST COMPLIANCE TABLE 1**

This table gives a summary of compliance and educative contacts and detected offences within the North Coast bioregion during the 2013/14 financial year.

* Pearling contacts are included in these totals.

** Contacts are classified according to the specific fishery, which is usually clearly delineated as being either commercial or recreational. The “other fishing related contacts within the community” category is used where multiple fisheries are contacted and it is not possible to accurately classify the contacts into one specific fishery – typically, the majority of contacts are these contacts are recreational in nature (e.g. personal contacts in marine parks), but contacts made in relation to fish kills, shark patrols and inspections of commercial fish wholesale and retail premises, etc, are also included in this category. This table includes contacts made by PV Houtman and PV Walcott while they were operating in the Bioregion.

*** Fishwatch reports are allocated to the District Offices relevant to the Bioregion. It is not possible to distinguish between calls relating to Inland Bioregions.

**** VMS (Vessel Days) represents the number of vessel days recorded in this bioregion. That is, a count for each day that each vessel was polled within the bioregion.
NORTH COAST COMPLIANCE FIGURE 1*

“On Patrol” Officer Hours showing the level of compliance patrol activity delivered to the North Coast Bioregion over the previous five years. The 2013/14 total gives the patrol hours in the bioregion that resulted in the contacts detailed in Table 1. (The totals exclude: time delivered by the Department’s large patrol vessels **PV Walcott**, **PV Houtman** and **PV Hamelin**; time spent on other compliance related tasks e.g. travel time between patrol areas, preparation and planning time etc.. Time spent in Marine Park sanctuary zones is also excluded because this time may overlap field time outside a sanctuary zone and as a result, the historic data is slightly lowered compared to that reported in previous reports.)
