LAKE BUNYIP

ABOUT THE BIOREGION

The oceanography of the North Coast Bioregion (North Coast Overview Figure 1) includes waters of Pacific Ocean origin that enter through the Indonesian archipelago bringing warm, low salinity waters polewards via the Indonesian Throughflow and Holloway Currents which flow seasonally and interact with Indian Ocean waters. The Integrated Marine and Coastal Regionalisation for Australia (IMCRA V 4.0) scheme divides this Bioregion into 8 meso-scale regions: Pilbara inshore, Pilbara offshore, North West Shelf, Eighty Mile Beach, Canning, King Sound, Oceanic Shoals and Kimberley (North Coast Overview Figure 1).

Ocean temperatures range between 22°C and 33°C, with localised higher temperatures in coastal waters, particularly along the Pilbara coastline. Fish stocks in the North Coast Bioregion are entirely tropical, with most having an Indo-Pacific distribution extending eastward through Indonesia to the Indian subcontinent and Arabian Gulf regions.

Coastal waters are generally low-energy in terms of wave action, but are seasonally influenced by infrequent but intense tropical cyclones, storm surges and associated rainfall run-off. These cyclone events generate the bulk of the rainfall, although the Kimberley section of the coastline does receive limited monsoonal rainfall over summer.

Significant river run-off and associated localised coastal productivity can be associated with cyclone events, with run-off ceasing during the Austral winter. Despite localised areas of high productivity the region is generally oligotrophic and large areas of the coastline receive no riverine input. The entire North Coast region is subject to very high evaporation rates (3 metres per year), although the Pilbara coastline is more arid than the Kimberley.

Other significant factors influencing coastal waters include the macro-tidal regime related to the wide continental shelf and the convergence of ocean currents. Spring tides range from greater than 11 metres along the Kimberley section of the coast down to more than 2 metres in the West Pilbara.

NORTH COAST OVERVIEW FIGURE 1

Map showing the North Coast Bioregion and IMCRA (V 4.0) meso-scale regions: Pilbara inshore, Pilbara offshore, North West Shelf, Eighty Mile Beach, Canning, King Sound, Oceanic Shoals and Kimberley.
As a result of these factors, the generally tropical low-nutrient offshore waters can, in the few small locations with rivers, be significantly influenced by rainfall run-off and tidal mixing to generate varying water quality in different sections of the North Coast Bioregion. Along the Kimberley coastline, waters are turbid and in areas locally productive, while the Pilbara Coast with its lower run-off and lesser tidal influence has the clear, low productivity waters more typical of the tropics.

The coastal geography of the various sections of the coastline also differs. The Kimberley Coast is highly indented, with bays and estuaries backed by a hinterland of high relief. Broad tidal mudflats and soft sediments with fringing mangroves are typical of this area. The eastern Pilbara Coast is more exposed than the Kimberley, with few islands and extensive intertidal sand flats. Softer sediments and mangroves occur around the river entrances. The western Pilbara coastline is characterised by a series of significant but low-relief islands including the Dampier Archipelago, Barrow Island and the Montebello Islands. Nearshore coastal waters include rocky and coral reef systems, creating significant areas of protected waters. West Pilbara shorelines also include areas of soft sediment and mangrove communities.

The potential threats and risks to IMCRA ecosystems are often similar. For simplicity, risk ratings were allocated by grouping the ecosystems into two broad groups; estuarine or marine. However, if a particular ecosystem is unique and/or is exposed to different or significant threats, risks were allocated to these ecosystems separately.

**SUMMARY OF ACTIVITIES POTENTIALLY IMPACTING THE BIOREGION**

**Climate Change**

Some of the key environmental trends that may be affecting ecosystems in WA include:

- Increasing frequency of El Niño/Southern Oscillation (ENSO) events;
- More years with a weaker Leeuwin Current;
- Increase in water temperature off the lower west coast of WA;
- Increases in salinity, which includes large annual fluctuations;
- Change in the frequency and location of storms (and rainfall) affecting the lower west coast; and
- Change in the frequency of cyclones (and summer rainfall) affecting the north-west coast.

The North Coast Bioregion is predicted to have relatively minor impacts from climate change, especially in the coming decade, compared to more southerly locations (Fletcher and Santoro 2012). The variables expected to drive climate change impacts include changes in water temperature, ocean currents, winds, rainfall, sea level, ocean chemistry and extreme weather conditions.

Climate change will impact the biological, economic, and social aspects of many fisheries, potentially in both positive and negative ways. Climate change can influence biological systems by modifying the timing of spawning, range and distribution, composition and interactions within communities, exotic species invasions and impacts, and the structure and dynamics of communities, including changes in productivity. Species distribution shifts are the most commonly reported changes and are often the easiest to recognise and measure. Changes in the distribution of key species are monitored in a national citizen-science program ([www.redmap.org.au](http://www.redmap.org.au)) in which the Department is a collaborator.

**Commercial Fishing**

There are 15 different State-managed commercial fisheries operating within the North Coast Bioregion. These fisheries target a variety of species including finfish, crustaceans, molluscs and echinoderms (North Coast Overview Figure 2). The principal commercial fisheries in the North Coast Bioregion focus on tropical finfish, particularly the high-value emperors, snappers and cods that are taken by the Pilbara trap, line and trawl fisheries and the Northern Demersal Scalefish Fishery (trap and line). The typical catch is in the order of 3,000 t annually, making these fisheries the most valuable finfish sector in the State, with an estimated annual value of at least $12 million. A number of other finfish fisheries operate in the Bioregion, including near-shore beach seining and gillnetting for barramundi and threadfin salmon (the Kimberley Gillnet and Barramundi Managed Fishery) and surface trolling for Spanish mackerel (the Mackerel Managed Fishery).

Another significant commercial fishery in this Bioregion is based on the collection of pearl oysters (*Pinctada maxima*) for use in the aquaculture production of pearls (see below). These are collected from fishing grounds primarily off Eighty Mile Beach, with smaller catches being taken around the Lacepede Islands (north of Broome).

The North Coast Bioregion also has a number of small, limited-entry trawl fisheries for prawns, producing about 200-300 t annually, valued at around $33 million. These fisheries include the Onslow, Nickol Bay, Broome and Kimberley Prawn Managed Fisheries (collectively referred to as the North Coast Prawn Managed Fisheries). Two small trap-based crab fisheries also exist in the Bioregion, targeting blue swimmer crabs in the Pilbara (the Pilbara Developing Crab Fishery) and mud crabs in the Kimberley (the Kimberley Developing Mud Crab Fishery). Sea cucumbers (also known as bêche-de-mer or trepang) are collected by hand by divers and waders throughout the Kimberley region as part of the Bêche-de-Mer Fishery. Catches are mainly comprised of two species, sandfish (*Holothuria scabra*) and redfish (*Actinopyga echinites*). The Trochus Fishery is a small fishery based on the collection of a single target species, *Tectus*...
*niloticus* from King Sound and the Buccaneer Archipelago. This fishery is operated by the Bardi Jawi and Mayala Aboriginal Communities, who have traditionally collected trochus in this area.

A traditional artisanal fishery also exists in an area around Roti Island, known as the MOU box. The MOU Box is an area within the Australian EEZ over which there is a bilateral agreement between the Governments of Australia and Indonesia. The MOU allows Indonesian fishers to continue fishing using traditional methods within Australian waters of the MOU Box under an agreement formalised in 1974.

Recreational Fishing

Recreational fishing is experiencing significant growth in the North Coast Bioregion, with a distinct seasonal peak in winter when the local population is increased by significant numbers of intra-state and inter-state tourists travelling through the area and visiting Onslow, Dampier Archipelago and Broome sections of the coastline. This adds to the increased recreational fishing effort resulting from people employed in the construction or operation of major developments in this region. Owing to the high tidal range, much of the angling activity is boat-based, with beach fishing limited to periods of flood tides and high water. The numerous creek systems, mangroves, rivers and beaches provide shore and small boat fishing for a variety of finfish species including barramundi, tropical emperors, mangrove jack, trevallies, sooty grunter, threadfin, cods and catfish, and invertebrate species including blue swimmer crabs, mud crabs and squid (North Coast Overview Figure 3). Offshore islands, coral reef systems and continental shelf waters provide recreational fishing opportunities for species including tropical snappers, cods, coral and coronation trout, sharks, trevally, tuskfish, tunas, mackerels and billfish.

Aquaculture

Aquaculture development in the North Coast Bioregion is dominated by the production of pearls from the species *Pinctada maxima*. An overview of aquaculture activities in the Bioregion is detailed in North Coast Overview Figure 4. A large number of pearl oysters for seeding is obtained from wild stocks and supplemented by hatchery-produced oysters, with major hatcheries operating at Broome and the Dampier Peninsular. Pearl farm sites are located mainly along the Kimberley coast, particularly in the Buccaneer Archipelago, in Roebuck Bay and at the Montebello Islands.
Aquaculture in the Kimberley region is dominated by barramundi farming within the Kimberley Aquaculture Development Zone, which was declared in August 2014. Located about 215 kilometres north-east of Broome, this zone encompasses almost 2,000 hectares of coastal waters within Cone Bay. The zone was declared after the completion of a strategic environmental study, which demonstrated the zone would be capable of producing 20,000 tonnes of finfish annually without significant environmental impact. MPA Fish Farms Pty Ltd, already established within the zone, has been granted an aquaculture licence to grow up to 15,000 tonnes of barramundi and other marine finfish per year on a 1,344-hectare site. A second aquaculture licence has been granted to Aarli Mayi Aquaculture Project Pty Ltd, which is authorised to grow 5,000 tonnes per annum.

A focus of aquaculture development is provided by the Departments’ Broome Tropical Aquaculture Park, which houses a commercial pearl oyster hatchery and the Kimberley Training Institute aquaculture training facility.

A company developing a project culturing marine microalgae for the production of bio-fuels, omega-3 lipid and protein biomass previously established a demonstration facility near Karratha. The company is currently assessing alternative sites for the project.

An indigenous project at One Arm Point operates a marine hatchery that focuses on a variety of ornamental and edible marine species.

Tourism

The marine tourism industry has experienced significant growth within the North Coast Bioregion, particularly along the Kimberley coast in recent decades. As coastal access is limited, tourists generally access the coast by boat from major population centres, such as Broome and Wyndham. Activities include charter fishing, diving, snorkelling, whale, turtle and dolphin watching and sightseeing cruises.

Sites of greatest interest to tourists include places to fish, areas for sightseeing and secluded locations for general relaxation. Luxury cruises take tourists along the coastline and increasingly out to isolated coral atolls for fishing and diving. Primary dive locations include the Rowley Shoals, Scott Reef, Seringapatam Reef, Ashmore Reef and Cartier Island.
Oil and Gas Activity

Offshore oil and gas is a large and growing industry in the North Coast Bioregion. Within the Bioregion, the Northern Carnarvon, Browse and Bonaparte Basins hold large quantities of gas, and multiple projects are in various stages of development, production and exploration (North Coast Overview Figure 5). The main disturbances associated with oil and gas exploration and production include noise pollution from seismic surveys, potential for fish movement/impact arising from seismic surveys, disturbance to the marine habitat through drilling and/or dredging activities, release of produced formation water, shipping and transport activities and oil spills.

Shipping and Maritime Activity

There are three major ports in the North Coast Bioregion: Broome, Dampier and Port Hedland (North Coast Overview Figure 5). The Port of Broome provides vital support for the Browse Basin offshore oil and gas industry. Other business includes livestock export, cruise liner servicing, coastal trading vessels, pearling, fishing and tourism charters. The Port of Dampier services both the land-based iron ore reserves and the offshore gas fields of the Carnarvon Basin. The Port of Port Hedland is the world’s largest bulk exporter, with 99% of the total cargo volume constituting exports. The port primarily exports iron ore, along with salt, livestock and petroleum products. There are eight other non-port authority ports in the North Coast Bioregion. In general, these ports and related export facilities are operated by resource companies. Most handle raw bulk commodity exports such as iron ore, crude oil and salt. An increase in shipping and port expansion associated with growth of the resources sector has potential implications for the marine environment. Potential threats include loss or contamination of marine habitats as a result of breakwater construction, dredging and sea dumping, oil spills, interactions between vessels and listed species and the introduction of marine pests.
Climate Change

Extensive work has been undertaken as part of a three-year FRDC-funded project (Caputi et al. 2015a,b) that assessed the effects of climate change on the marine environment and key fisheries, as well as management implications. Although these studies focused on Bioregions more susceptible to increases in sea surface temperature (SST) to the south, there were no significant effects expected from climate change on the species selected (Caputi et al. 2015a,b). However, if a southward expansion in the range of Narrow-Barred Spanish Mackerel occurred then it is possible that the total biomass of this species in Western Australia may increase due to various factors associated with breeding and availability of suitable habitats (Caputi et al. 2015b).

The Department completed a pilot project aimed at establishing resource condition monitoring protocols for the Pilbara and Kimberley. The establishment of standardised long term resource monitoring programs is fundamental to understanding and thus managing the impacts of climate change on marine resources. The project focused on a literature review relating to the coastal and marine environments in the Pilbara and Kimberley. The literature review has highlighted those areas of research that are lacking from the region. The vast and remote coastline of the region dictates that remote sensing (satellite imagery and aerial photography) is likely to be the primary tool for resource condition monitoring. The project concentrated on developing remote sensing as a monitoring tool, and developing a suite of resource condition indicators that represent the health of the numerous marine and coastal environments, and set bench marks for which to assess environmental change within the Pilbara and Kimberley.

Spatial Closures

Extensive fisheries closures in coastal and most offshore waters have been introduced to manage finfish trawling by Australian vessels (North Coast Overview Figure 6). However, trawling is still permitted in a small number of limited locations, which in total represent less than 11% of the shelf waters (North Coast Ecosystem Management Table 1; see specific commercial trawl fishery reports elsewhere in this volume). This activity is carefully managed to ensure that impacts are acceptable. The trawling is subject to Ecologically Sustainable Development (ESD) requirements in accordance with the Commonwealth Government ‘Guidelines for the Ecologically Sustainable Management of Fisheries’ under the Environment Protection and Biodiversity Conservation Act, 1999. The extent of these areas means that 41% of the entire shelf region of the North Coast Bioregion could be classified as a marine protected area with an IUCN category of IV or higher (as per Dudley, 2008 and Day et al 2012; North Coast Ecosystem Management Table 1).

In addition to these habitat related marine protected area closures, the Bioregion has a number of other marine protected areas with various management objectives, summarised in North Coast Overview Figure 7. These include the Montebello and Barrow Islands and the Rowley Shoals proclaimed under the Conservation and Land Management Act 1984 (see North Coast Ecosystem Management Figure 2), and closures to fishing under section 43 of the Fish Resources Management Act 1994 at Point Samson and the wreck of the Kunmunya Samson II (Delambre Reef). The Department of Fisheries has also participated in the marine conservation reserve planning process in this Bioregion and has established baseline and ongoing monitoring and research to underpin ecosystem management. There is considerable interest in developing further marine protected areas within the Kimberley region, and the State Government is developing management plans, Indigenous Land Use Agreements (ILUA) and zoning arrangements for marine protected areas at Eighty Mile Beach, Roebuck Bay, Horizontal Falls and the North Kimberley. The proposed Dampier Archipelago marine conservation reserves are still under consideration by Government. The Department continues to work closely with relevant agencies and stakeholders to develop strategies to minimize environmental impacts in the marine environment. This includes participation in the Kimberley Science and Conservation Strategy developed with the Department of Biodiversity, Conservation and Attractions (DBCA) and collaboration on relevant Western Australian Marine Science Institute (WAMSI) Kimberley Marine Research Program projects.

The Commonwealth Government has also undertaken a Marine Bioregional Planning process for Commonwealth waters between Shark Bay and the Northern Territory border. The federal minister for the environment is yet to announce the final reserve network for the North-West which spans the North Coast and Gascoyne Bioregions.
NORTH COAST BIOREGION

NORTH COAST ECOSYSTEM MANAGEMENT TABLE 1
The areas and proportions of the North Coast Bioregion making up State Waters and all continental shelf waters, out to 200 m depth, which are consistent with the IUCN criteria for classification as marine protected areas. This table does not yet include the closures that may be implemented by the Commonwealth as part of their marine planning zones.

ECOSYSTEM MONITORING AND STATUS

In order to assess the adequacy of management arrangements aimed at ensuring sustainability of the ecological assets within the North Coast Bioregion, the Department must identify and monitor trends in the condition of these resources. This is achieved through application of an Ecosystem Based Fisheries Management (EBFM) framework (Fletcher, et al., 2010) to identify, in a hierarchical manner, the key ecological resources that require ongoing monitoring and assessment. (See How to Use section for more details). These key ecological assets identified for the North Coast Bioregion are identified in North Coast Overview Figure 8 and their current risk status reported on in the following sections.
External Drivers

External factors include factors impacting at the Bioregional-level that are likely to affect the ecosystem as whole and may not fall within the direct control of Fishery legislation (e.g. climate change). An understanding of these factors, which are typically environmental (cyclones, ocean currents) is necessary to fully assess the performance of the ecological resource. The main external drivers identified with potential to affect the North Coast Bioregion include climate, introduced pests and diseases and oil and gas development activities.

Climate

<table>

<tr>
<th>External Drivers</th>
<th>Current Risk Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced Pests</td>
<td>LOW</td>
</tr>
<tr>
<td>Introduced Diseases</td>
<td>LOW</td>
</tr>
</tbody>
</table>

The increase in international shipping movement and dredging activity associated with resource development in the North Coast Bioregion is considered to present a low risk to the marine environment because of the potential for the introduction of non-indigenous marine organisms, including animals, plants, pathogens and diseases. The Department implements a range of monitoring and research activities in the Bioregion, focussed on early detection of potential marine pests.

Oil and Gas Development Activity

<table>
<thead>
<tr>
<th>External Drivers</th>
<th>Current Risk Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oil and Gas Development</td>
<td>LOW</td>
</tr>
</tbody>
</table>

While there are a number of specific oil and gas related offshore developments that are proposed in this region, at the overall ecosystem level there is only a low risk.
that the ecosystem will be altered measurably. Some of the risks identified (e.g. increased turbidity) are being examined under WAMSI 2 projects. In addition, State and Commonwealth marine parks, including totally protected zones, are currently in place or planned.

Captured Species

**FINFISH**

The principal fisheries in the North Coast Bioregion focus on tropical finfish, particularly the high-value emperors, snappers and cods. These species are taken by the Pilbara Demersal Scalefish Fishery (trawl, trap and line sectors) and the Northern Demersal Scalefish Fishery (trap and line). The typical catch is in the order of 3000 t annually at an estimated annual value of around $12 million, making these fisheries the most valuable finfish sector in the state. A number of other finfish fisheries operate in the Bioregion, including near-shore beach seining and gillnetting for barramundi and threadfin salmon (the Kimberley Gillnet and Barramundi Managed Fishery) and surface trolling for Spanish mackerel (the Mackerel Managed Fishery).

Indicator species which reflect the characteristics of the broader exploited stocks are monitored in order to assess ecological risk to the ranges of species targeted.

**Estuarine/ Nearshore (0-20m depth)**

<table>
<thead>
<tr>
<th>Captured Species</th>
<th>Aquatic zone</th>

</tr>
</thead>
<tbody>
<tr>
<td>Finfish</td>
<td>Estuarine/Nearshore</td>
<td>MODERATE</td>
</tr>
</tbody>
</table>

The Kimberley Gillnet and Barramundi Managed Fishery (KGBF) is the only commercial finfish fishery operating in the nearshore and estuarine zones of the North Coast Bioregion. The primary target species are barramundi and threadfin salmon. Stocks of barramundi and threadfin salmon are considered to be at acceptable levels.

**Inshore (shelf) Demersal (20-250 m depth)**

<table>
<thead>
<tr>
<th>Captured Species</th>

</tr>
</tbody>
</table>

There are four State-managed commercial fisheries in the Inshore Demersal region, which use multiple methods to target demersal fish stocks. These fisheries include: The Pilbara Fish Trawl (Interim) Managed Fishery (PFTIMF); The Pilbara Trap Managed Fishery (PTMF); The Pilbara Line Fishery (PLF); and The Northern Demersal Scalefish Managed Fishery (NDSF).

These fisheries all target the tropical demersal scalefish suite in the Pilbara and Kimberley Inshore Ecosystem and are collectively referred to as the Pilbara Demersal Scalefish Fisheries (PDSF) and Kimberley Demersal Scalefish Fisheries (KDSF). The trawl fisheries land the largest component of the catch, comprising more than 50 scalefish species.

**Pelagic**

<table>
<thead>
<tr>
<th>Captured Species</th>
<th>Aquatic zone</th>

</tr>
</thead>
<tbody>
<tr>
<td>Finfish</td>
<td>Pelagic</td>
<td>MODERATE</td>
</tr>
</tbody>
</table>

The Spanish Mackerel stock in this region targeted by the Mackerel Managed Fishery is at acceptable levels, and there are few other pelagic fish that are impacted.

**INVERTEBRATES**

A significant commercial invertebrate fishery in this Bioregion, is the Pearl Oyster Managed Fishery, which is based on the collection of pearl oysters (*Pinctada maxima*) for use in the aquaculture production of pearls. The North Coast Bioregion also has a number of small, limited-entry trawl fisheries for prawns, producing around 700 t annually and valued at around $10 million. Two small trap-based crab fisheries also exist in the Bioregion, targeting blue swimmer crabs in the Pilbara (the Pilbara Developing Crab Fishery) and mud crabs in the Kimberley (the Kimberley Developing Mud Crab Fishery). Sea cucumbers (also known and bêche-de-mer or trepang) are collected by hand by divers and waders throughout the Kimberley region. Catches are mainly comprised of two species, sandfish (*Holothuria scabra*) and redfish (*Actinopyga echinites*). The Trochus Fishery is a small fishery based on the collection of a single target species, *Tectus niloticus* from King Sound and the Buccaneer Archipelago. This fishery is operated by the Bardi Jawi and Mayala Aboriginal Communities, who have traditionally collected trochus in this area.

**Crustaceans**

<table>
<thead>
<tr>
<th>Captured Species</th>
<th>Aquatic zone</th>
<th>Ecological Risk</th>
</tr>
</thead>
<tbody>
<tr>
<td>Crustaceans (Crabs)</td>
<td>Inshore/ Nearshore</td>

<td>Inshore</td>
<td>MODERATE</td>
</tr>
</tbody>
</table>

There is a small amount of fishing for mud crabs and blue swimmer crabs in some estuarine and inshore areas and its ecological risk is considered to be low.

There are a number of separate prawn stocks and fisheries within this Bioregion and each has limited entry, seasonal and area closures. Annual recruitment to these stocks is variable, which combined with the higher costs of operating in this region, has resulted in fishing effort being much lower in recent years.
The North Coast Bioregion

Molluscs

<table>

The majority of the effort for bêche-de-mer has been expended in the Kimberley region, although there have been several years with substantial effort directed into the Pilbara region.

Listed Species

A number of endangered, threatened and protected (ETP) species can be found within the North Coast Bioregion, including cetaceans, dugongs, marine turtles, sea snakes, elasmobranchs, seahorses and pipefish, crocodiles and seabirds and migratory shorebirds. These species are protected by various international agreements and national and state legislation. International agreements include:

- Convention on the Conservation of Migratory Species of Wild Animals 1979 (Bonn Convention);
- The Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES);
- The Agreement between the Government of Australia and the Government of Japan for the Protection of Migratory Birds in Danger of Extinction and their Environment 1974 (JAMBA);
- The Agreement between the Government of Australia and the Government of the People’s Republic of China for the Protection of Migratory Birds and their Environment 1986 (CAMBA);
- The Agreement between the Government of Australia and the Government of the Republic of Korea on the Protection of Migratory Birds 2007 (ROKAMBA);
- Any other international agreement, or instrument made under other international agreements approved by the environment minister including the EBPC Act 1999.

Primary pieces of national and Western Australian legislation include the Commonwealth Environment Protection and Biodiversity Act 1999 (EPBC Act), the Western Australian Wildlife Conservation Act 1950 (WC Act), and the Fish Resources Management Act 1994 (FRMA).

Fisheries in the region that have reported interactions with ETP species include trawl fisheries (the Onslow Prawn Managed Fishery (OPMF), the Nickol Bay Prawn Managed Fishery (NBPMF), the Pilbara Fish Trawl Fishery) and the Kimberley Gillnet Barramundi Fishery (KGBF). ETP interactions with the trawl fisheries are few, due to fishing arrangements, such as the use of bycatch reduction devices and the separation of trawling activities from most ETP species’ primary habitat. Similarly, fishers in the KGBF actively avoid capturing ETP species; however, a small amount of interactions have been reported with crocodiles and sawfish.

<table>
<thead>
<tr>
<th>Listed species</th>
<th>Risk</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fish</td>
<td>MODERATE</td>
</tr>
</tbody>
</table>

The sawfish (Pristidae), speartooth shark (*Glyphis glyphis*) or the northern river shark (*Glyphis garricki*) are incidentally captured in small numbers by net fishing and trawlers in some areas of the Kimberley region. The area of these fisheries in which sawfish are vulnerable to capture is small relative to the total range of each species, suggesting limited impacts on each population. However, elasmobranchs grow and reproduce slowly, and even low levels of fishing mortality may be unsustainable.

Sea horses and pipefish are occasionally captured in trawl nets and fish/crab traps. The areas of each fishery in which syngnathids and solenostomids are vulnerable to capture is small relative to the total distribution of the species, which includes waters inshore of the fishery and fishery closed areas, as well as structured habitats where trawling does not occur.

Recent video observations indicate that the potato cod is present in high numbers at discrete locations within the Kimberley region where the NDSF operates. Potato cod (*Epinephelus tukula*), a totally protected species, rarely enter fish traps due to their large size and girth limiting their capacity to pass through the entrance funnel into fish traps.

---

1 Note that being on a listed species list does not automatically indicate that a species is either threatened or endangered.

2 Further information on the CMS, JAMBA, CAMBA and ROKAMBA is provided at www.environment.gov.au/biodiversity/migratory/index.html
Dolphins are incidentally captured by the Pilbara fish trawl fishery. To assist in mitigation of shark, reptile and cetacean bycatch, species-specific responses to three bycatch reduction device (BRDs) configurations were investigated using both in situ subsurface and onboard observations. The upward inclined exclusion grid significantly improved the escape proportions for most sharks by 21-29%. All BRDs were highly effective in reducing reptile (turtles and sea snakes) bycatch, but irrelevant for the few sawfish (n = 13) that readily entangled in the anterior of the net. Cetacean (bottlenose dolphins only) interactions with BRDs were very rare (n = 7) despite high levels of attendance and depredation during trawling. Loss of targeted teleosts through the BRDs was also very rare (1.3% of day trawls). The study also provided evidence that the subsurface expulsion of megafauna in poor condition is negligible. The Pilbara fish trawl fishery operates under WTO with conditions around dolphin and sawfish interactions and monitoring.

Sea snakes and turtles are encountered occasionally in trawl catches. Both of these taxa are typically returned to the sea alive. Grids are now compulsory on trawl nets, which has largely eliminated the capture of any turtle or other large animal.

Crocodiles are occasionally captured in nearshore/freshwater fisheries’ nets and are typically are released alive.

Anecdotal information from Lake Argyle fishers suggests that interactions with birds and crocodiles are very low. Additionally, the fishery is closed from 1 November to 31 December each year, during a high-use period for protected migratory birds.

### Habitats and Ecosystems

Coastal geography is extremely variable within the North Coast Bioregion and its identified meso-scale ecosystems include a range of key habitats in depths of less than 40 m (where the vast majority of relevant fisheries resources are located and fishing activities are undertaken in this Bioregion) which include:

#### Mangroves:
Mangroves occur throughout the Bioregion, and within the Kimberley, are considered to be very well developed and relatively pristine. The mangrove communities of Roebuck Bay and Eighty Mile Beach have been listed as Ramsar Wetlands of International Significance mainly due to the numbers of migratory wading birds they support.

#### Seagrasses:
Seagrasses are mainly tropical species. Twelve species have been identified throughout the North Coast Bioregion, including one endemic species (*Cymodocea angustata*). Within the Bioregion, seagrasses are generally found in shallow water environments near the mainland coast and offshore reefs and shoals.

#### Algae:
Algal growth is restricted by the limited presence of hard substrates on the North West Shelf. Throughout the Kimberley, the effects of strong tidal currents and high turbidity result in low macroalgal diversity. Surveys in the Kimberley have identified 72 species of macroalgae in the southern Kimberley and 90 species (not including coralline algae) in the northern Kimberley, most of which are widespread tropical taxa.

#### Sponges and Filter-Feeding Communities:
Sponges are found from tidal areas to the deep waters of the Abyssal Plain and generally occur as part of a mixed filter-feeding community. Species richness varies considerably throughout the Bioregion, with both relatively low-diversity communities (<25 species, e.g. Rowley Shoals) and exceptionally rich communities (>250 species, e.g. Dampier-Port Hedland regions). Sponge communities throughout the Bioregion are also broadly different. For example, a study by the Western Australian Museum found more than half the sponges identified at Mermaid, Scott and Seringapatam Reefs were unique to a single reef (WAM, 2006).

#### Coral Reefs:
Coral reefs in the Bioregion fall into two general groups: the fringing reefs around coastal islands and the mainland shore and large platform reefs, banks and shelf-edge atolls on the mid and outer shelf. North of Cape Leveque, the Kimberley supports extensive nearshore reef systems. Areas of fringing reef development include islands in the Buccaneer Archipelago, the Heyward island group, islands of the Bonaparte Archipelago and off mainland shores of Cape Voltaire and Cape Bougainville. Coral diversity is typically high, with surveys of the Buccaneer Archipelago having recorded 280 species of coral from at least 55 genera. Coral reefs are also well developed around offshore island such as Ashmore, Cartier, Hibernia, Seringapatam and Scott Reefs, Browse Island and the Rowley Shoals.

#### Sand/Mud:
Embayments along the Kimberley are known to have extensive muddy tidal flats and the majority of the offshore area is dominated by soft sediment seabeds, which are mainly sand/mud with occasional patches of coarser sediments. In depths beyond 40 m, ecosystems include hard- and soft-bottom benthic communities, sand banks and pelagic communities. Given the low levels of activities in these depths, there is little detailed information on these environments.

A high level of protection of the ecosystems and habitats within the North Coast Bioregion is ensured based on the limited area of the Bioregion that is available to commercial trawl fishing activity (North Coast Bioregion Overview Figures 6 and 7). If areas that are not trawled are taken into account, 89% of statewide benthic habitats out to the 200 m isobath are protected and may never have been trawled (North Coast Ecosystem Management Table 1). In addition to fisheries-related closures, the North Coast Bioregion...
NORTH COAST BIOREGION

has a number of marine protected areas described under the preceeding “spatial closures” section.

The Department identifies and monitors trends in the condition of ecosystems and their associated habitats to ensure the long term sustainability of both these key ecological assets and the fisheries that depend on them.

### Habitats

<table>
<thead>
<tr>
<th>Habitats</th>

<td>LOW</td>
</tr>
<tr>
<td>Pilbara</td>
<td>Marine</td>
<td>MODERATE</td>
</tr>
</tbody>
</table>

The majority of these fishing activities occur in mud/sand habitats in estuaries, tidal creeks and embayments. Trawl activities are considered to have the highest relative impact of the methods used within the bioregion which also includes low impact activities of trap, gillnets and hand collection based fisheries. However, the spatial extent of trawling activities is small, and there are a variety of measures in place to manage any impacts. The spatial distribution of all fishing activities are also managed through the use of seasonal and area closures to protect sensitive habitats.

<td>MODERATE</td>
</tr>
</tbody>
</table>

There are a number of oil and gas related offshore and onshore developments that exist or are proposed in this bioregion. While some specific areas may be locally impacted, these still only pose a low risk to the overall ecosystem of this Bioregion.

Given the large areas closed to both trawling and to all commercial fishing, there is a low risk that the level of fishing in this region is changing the regional-level community structure to an unacceptable level. Assessments of the community structure and trophic level of all commercially caught fish species in the region over the past 30 years found no evidence that there have been any systematic changes. (Hall and Wise 2011). The majority of catch from each fishery is comprised of the main target species, and catch compositions have remained stable throughout the history of each fishery. None of the main target species are known to be involved in any strong ecological interactions and their removal at current rates is unlikely to seriously or irreversibly alter community structure.
OVERVIEW

The four northern prawn managed fisheries (Kimberley, Broome, Nickol Bay and Onslow) all use low opening, otter prawn trawl systems to target western king prawns (*Penaeus latisulcatus*), brown tiger prawns (*Penaeus esculentus*), and endeavour prawns (*Metapenaeus endeavouri*). High opening, otter trawl systems are also used when targeting banana prawns (*Penaeus merguiensis*) which is the target species for two of these fisheries. Management of these fisheries is based on input controls, including limited entry, gear controls (maximum headrope units), seasonal and area openings and closures. The fisheries have Commonwealth export approval for the next ten years.

CATCH AND LANDINGS

**Kimberley Prawn Managed Fishery (KPMF)**

The total landings in 2016 for the KPMF were 155 t, similar to the levels caught during the past 8 years. However the catch of 135 t of banana prawns was the lowest in over 35 years, with 17 t of brown tiger prawns and 3 t of endeavour prawns also taken (North Coast Prawn Figure 1). There are two fishing periods for the complete season (April and May, then from August to December). Fishing occurred in both fishing periods however the second part of the season had much reduced fishing effort compared to previous years. Negligible quantities of byproduct were reported.
NORTH COAST PRAWN FIGURE 1.
Annual prawn landings (t) and fishing effort (total adjusted hours) for the Kimberley Prawn Managed Fishery 1980-2016.

NORTH COAST PRAWN FIGURE 2.
Annual prawn landings (t) and fishing effort (total adjusted hours) for the Nickol Bay Prawn Managed Fishery 1985-2016.

Broome Prawn Managed Fishery (BPMF)
Extremely low fishing effort was recorded as only trial fishing was undertaken by one boat to investigate whether commercial fishing was warranted. This resulted in negligible landings of western king prawns with no byproduct recorded.

Nickol Bay Prawn Managed Fishery (NBPMF)
The total landings of major penaeids for the 2016 season were 17 t, the second lowest catch since 1966 (North Coast Prawn Figure 2). This comprised 16 t of banana prawns, which was below the predicted range (35 – 53 t, based on updated data), 1 t of brown tiger prawns, negligible quantity of endeavour prawns and no recorded landings of western king prawns.

Onslow Prawn Managed Fishery (OPMF)
The total landings of major penaeids for the 2016 season were 3 t, comprising 2 t of banana prawns, and <1 t each of brown tiger prawns and endeavour prawns. No western king prawns were recorded as landed.
INDICATOR SPECIES ASSESSMENTS AND STOCK STATUS

Kimberley Prawn Managed Fishery – Banana prawns (Sustainable-Adequate)

Due to a change associated with the fleet structure and economics of fishing, there has been a marked reduction in the number of fishers each year with fishing effort (boat-days) below historical levels since 2005 (North Coast Prawn Figure 1). However, total catches have generally been in line with seasonal catch predictions. The breeding stock is considered sustainable-adequate.

Broome Prawn Managed Fishery – Western king prawns (Sustainable-Adequate)

No fishing takes place during the breeding season and there is minimal overlap of fishing on the breeding stock due to the widespread nature of this species and the current low level of fishing effort. Higher average water temperatures appear to be having a negative effect on western king prawn catches in recent years in the north coast prawn fisheries. However, the breeding stock is considered sustainable-adequate.

Nickol Bay Prawn Managed Fishery – Banana prawns (Sustainable-Adequate)

On the basis of annual trends in catch, effort, and catch rates, the outputs of preliminary stock production models and a biomass dynamics model, it is considered that the stock is being fished at a sustainable level with the breeding stock considered sustainable-adequate.

Onslow Prawn Managed Fishery – Brown Tiger and Western King Prawns (Sustainable-Adequate)

One boat fished in the OPMF in 2016. However, because this boat can operate in other fisheries where catches were more profitable, this fishery recorded very low effort and catch. Therefore the breeding stocks of brown tiger and western king prawns were protected and are considered sustainable-adequate.

BYCATCH AND PROTECTED SPECIES INTERACTIONS

Bycatch levels for all these fisheries are relatively low by tropical trawl fishery standards, with few species of significance to other fishing sectors being taken. In addition to grids, fish escape secondary bycatch reduction devices (FEDs) (square mesh panels) were implemented in all nets in 2005. All boats also use hoppers (in-water catch sorting systems), which adds another level of improvement for bycatch survival and product quality. Low risk.

While protected species including dugongs, turtles and sea snakes occur in the general area, only sea snakes and occasionally turtles are encountered in the trawl catches. Both species are typically returned to the sea alive. Grids have largely eliminated turtle and other large animal captures. Low risk.

Protected species interactions recorded in the daily logbooks for each fishery in 2016 are:

Kimberley: 72 sea snakes were recorded as being caught with 58 returned to the sea alive, 10 with status unknown and 4 returned dead. Four sawfish were recorded as captured with three returned to the sea alive and 1 recorded dead.

Broome: The fishery operates in relatively deep water. This, combined with the short season, restricted trawl area and very low effort, results in minimal interaction, and no interactions were reported.

Nickol Bay/Onslow: There were no reported protected species interactions for either fishery, and this was likely due to the limited effort applied in these two fisheries this season.

HABITAT AND ECOSYSTEM INTERACTIONS

Owing to the predominantly mud and sand habitats of the trawl grounds, the trawl gear has relatively little physical impact. Overall, the nature of these fisheries and controls on effort indicate that its environmental impact is likely to be low. The area fished in the four northern prawn fisheries ranged from 1.4% in the KPMF to <1% in the BPMF, within the boundaries of these fisheries. Low risk.

Prawn species are generally managed at relatively moderate levels of annual harvest, and this has declined in recent years for economic reasons. Therefore, the impact of the catch on local food chains is unlikely to be significant in view of the high natural mortality of prawns, the extent of non-trawled nursery areas in each fishery and variable biomass levels of prawns resulting from variable environmental conditions such as cyclone events. Low risk.

SOCIAL AND ECONOMIC OUTCOMES

Social

The estimated employment in 2016 was 40 to 50 people including skippers and other crew for all north coast prawn fisheries combined.

Economic

Ex-vessel (beach) prices for prawns vary, depending on the type and quality of product and the market forces operating at any one time. The total estimated value of the fisheries excluding byproduct are; KPMF - $2.0 M, NPMF - $0.2 M, BPMF and OPMF - negligible.
GOVERNANCE SYSTEM

Annual Catch Tolerance Levels

KPMF: 240 - 450 t (Acceptable). Banana prawn landings were below their allowable range as well as the predicted range due to low fishing effort because of expected low landings (low rainfall).

NPMF: 90 - 300 t (Acceptable). All catches were below their tolerance ranges with banana prawns well below their predicted range. Due to low rainfall and the low predicted catch, fishing effort was directed into other prawn fisheries.

OPMF: 60-180 t (Acceptable). Effort and catch were minimal in 2016.

Harvest Strategy

Management arrangements for all four fisheries are designed to keep fishing effort at levels that will maintain a sufficient spawning biomass of prawns. For the KPMF, an effort cap of 1500 vessel days is set for the two parts of the season. For the NBPMF, a conservative harvesting strategy of the banana prawn resource provides protection from recruitment overfishing, allowing adequate spawning biomass to survive to the key spawning period each year by opening the key fishing grounds in May. For the BPMF, trial fishing is undertaken to assess the stock level of western king prawns prior to commercial fishing commencing thus retaining spawning biomass. Bycatch reduction devices, including grids and FEDs (are mandatory under the EPBC Act).

Compliance

It is a requirement that all vessels in these fisheries are fitted with an Automatic Location Communicator (ALC). The implementation of an ALC enables the Department of Primary Industries and Regional Development (Department) to monitor the fleet using a Vessel Monitoring System (VMS) and manage compliance with temporal and spatial closures. The Department also undertakes regular vessel inspections to ensure fishing is being undertaken in accordance with the governing legislation (e.g. gear requirements, catch reporting).

Consultation

Biannual meetings between the Department, WAFIC and licence holders are held to consider the status of the stocks and recommend the opening and closing dates and fishing arrangements that operate within the season.

Consultation with non-fisher stakeholders is undertaken in accordance with the Department’s Stakeholder Engagement Guidelines.

Management Initiatives/Outlook

The Department is currently investigating the potential of a review of the KPMF in 2017/18. The review proposes to unitise effort days to address latent effort and allow for improvements in the fishery’s seasonal management arrangements.

EXTERNAL DRIVERS

A positive relationship has been observed with summer rainfall and banana prawn landings, particularly in the NBPMF (Caputi et al. 2014a).

High water temperatures are also having a negative effect on western king prawn catches in recent years (Caputi et al. 2014b, 2016) which may be impacting those northern prawn fisheries that target western king prawns. Brown tiger prawns were ranked as a high risk to climate change effects and western king prawns as moderate-high and will need to be monitored (Caputi et al. 2014b, 2015).

REFERENCES

OVERVIEW

The Kimberley Gillnet and Barramundi Fishery (KGBF) operates in the nearshore and estuarine zones of the North Coast Bioregion and extends from the WA/NT border (129ºE) to the top end of Eighty Mile Beach, south of Broome (19ºS). It encompasses the taking of any fish by gillnet in inshore waters and the taking of barramundi (Lates calcarifer) by any means. The principal species landed are barramundi (Lates calcarifer) and two species of threadfin (king threadfin Polydactylus macrochir and blue threadfin Eleutheronema tetradactylum). Small quantities of Elasmobranchs (sharks and rays), black jewfish (Protonibea diacanthus) and tripletail (Lobotes surinamensis) are also landed.

The main areas of operation for the commercial fishery are the river systems and tidal creek systems of the Cambridge Gulf (including Ord River), the Ria coast of the northern Kimberley (six small river systems), and King Sound. Access to the KGBF is limited to four licences, following the buyout of the two licences from the Broome Coast (Roebuck Bay) area in 2013. Commercial fishing is now prohibited between the southern boundary if the fishery (19º00′ S) to north of Willie Creek (17º44′ S). Fishing is also restricted to within three nautical miles of the high water mark for the remainder of the fishery. There are commercial fishing area closures around major town sites and recreationally important fishing locations, namely Derby Jetty, the Fitzroy River, and all its creeks and tributaries south of 17º27′ S, Whistle Creek and Admiral Bay, and the lower Ord River upstream of Adolphus Island.

CATCH AND LANDINGS

The total reported catch of all species in the KGBF in 2016 was 74.6 tonnes (t) (North Coast Nearshore and Estuarine Table 1). The total landings of barramundi in 2016 were 50.8 t (North Coast Nearshore and Estuarine Table 1, Figure 1), slightly less than the 2015 catch of 52.4 t. The 2016 landings of threadfin from the KGBF were 19.4 t (North Coast Nearshore and Estuarine Table 1, Figure 1), down from the 26.2 t reported in 2015.

The top 10 nearshore and estuarine species (or species groupings) in the North Coast represented 83% of the total boat-based recreational catch (kept by numbers) in 2015/16. The estimated boat-based recreational harvest range for the top 10 nearshore and estuarine species in the North Coast was steady in 2015/16 compared with estimates from previous statewide surveys (95% CI 20–35 tonnes compared with 15–27 in 2013/14 and 20–36 in 2011/12) (Ryan et al. 2017). No recent estimates of shore-based recreational catches are available.
**INDICATOR SPECIES**

**ASSESSMENTS AND STOCK STATUS**

**Barramundi (Sustainable-Adequate)**

The barramundi catch in 2016 was 50.8 t, above the target catch range but did not exceed the limit range. The catch rate reduced from 136.1 kg/block day in 2015 to 96 kg/block day in 2016, but remains high relative to catch rates recorded prior to 2011 (North Coast Nearshore and Estuarine Figure 2).

The above evidence indicates that the biomass of these stocks is unlikely to be recruitment overfished and that current levels of fishing mortality (catch) are unlikely to cause the stock to become recruitment overfished. Thus the breeding stock is classified as **sustainable-adequate**.

**King threadfin (Sustainable-Adequate)**

Threadfin catches are dominated by king threadfin. Catch of king threadfin in 2016 was 19 t, lower than that reported in previous years and well below the average of 74.5 t for the 10-year period from 2004–13. This is due to the low effort levels now available in the fishery. This follows the removal of two fishing licenses from the Broome coast area, with this area now closed to commercial fishing. The lower commercial catches in recent years (post closures) are relatively stable. King threadfin are landed by recreational and charter fishers, but only in small quantities (1 t). The above evidence indicates the biomass of this stock is unlikely to be recruitment overfished and that the current fishing pressure is unlikely to cause the stock to become recruitment overfished.

On the basis of the evidence provided above, the breeding stock of King Threadfin is classified as **sustainable-adequate**.

NORTH COAST NEARSHORE AND ESTUARINE FIGURE 2
The annual catch and catch per unit effort (CPUE, kg block day$^{-1}$) for barramundi from the KGBF over the period 1990 to 2016. The upper and lower bounds of the target commercial catch range for barramundi are shown by the shaded catch area between 33 and 44 tonnes.

**BYCATCH AND PROTECTED SPECIES INTERACTIONS**

**Bycatch**

The fishery operates at a relatively low intensity over a wide area of the Kimberley region, specifically targeting barramundi and threadfin. The fishing gear uses large mesh sizes, and hence does not generate a significant bycatch of species important to other sectors, but does take some sharks and rays. Where practicable, sharks and rays are released alive. However, there is some mortality of sharks and rays associated with gillnet capture. Because of the low spatial density of fishing effort relative to the widespread distribution of these species and the size-selectivity of the permitted mesh sizes, these impacts impose a negligible risk to the stocks involved. **Negligible** risk.

**Protected species**

The fishing gear used for this fishery (gillnets) is known to result in the occasional bycatch of protected crocodiles (*Crocodylus porosus*) and sawfish (Family Pristidae). These species are generally released alive or avoided as far as is practicable. Because of the low effort levels and the low spatial intensity of fishing effort, these impacts are unlikely to pose a significant threat to the sustainability of the stocks of these species. In 2016, listed species interactions were reported for both crocodiles and sawfish. Given the fishery’s overall low effort levels, particularly inside the freshwater drainages in which these species are most likely to occur, the fishing operations of the KGBF are unlikely to pose a significant threat to the sustainability of the stocks of these species. Effort levels inside freshwater drainages will be monitored. **Low** risk.

**HABITAT AND ECOSYSTEM INTERACTIONS**

This fishery poses a negligible risk on the nearshore and estuarine ecosystem of the Kimberley region due to the low spatial density of fishing effort. The fishing gear has minimal impact on the habitat. The area and habitat fished is subject to extreme tidal currents and associated effects and is typically mud flat areas.

**SOCIAL AND ECONOMIC OUTCOMES**

**Social**

During the 2016 season (February to November), four vessels fished in the KGBF with an average crew level of approximately 2.5 people, with an estimate of at least 10 people directly employed in the fishery. There was additional employment through local processors and distribution networks. The fishery provides fresh fish for local communities and the tourism industry throughout the Kimberley region. A significant number of recreational and charter anglers also fished across the region. Recreational fishing attracts many visitors to the North Coast Bioregion, particularly in nearshore areas over the winter dry season (April – October). This provides employment through local charter fishing services and fishing tackle outlets around key population centres, as...
well as more remote charter operations offering
wilderness fishing experiences in the north Kimberley
region. The social amenity definition for the KGBF is
important (this fishery is an important asset locally
and/or the use or existence of the asset is important to
the broader community).

Economic
The fishery’s score value in 2016 was estimated to be
Level 1 (i.e. Risk level – Low; Economic value – < $1
million). The establishment of new marine parks may
impact on the future economic viability of the KGBF.

GOVERNANCE SYSTEM
Annual Catch Tolerance Levels (Acceptable)
The target commercial catch range was calculated
based on catch information from 1989 – 1999, a period
during which the fishery was stable and levels of
exploitation were considered to have been sustainable.
However, the target catch range for barramundi has
recently been revised to be consistent with the
reference points and control rules adopted for other
fisheries. The current approach specifies this range as
the values within the minimum and maximum catches
observed during the reference period. The threshold
values for the target commercial catch range have been
calculated as being within the range of 33 – 44 t, with a
limit reference range of 23-54 t. Monthly catch and
effort data from the commercial fishery are used to
assess the status of barramundi populations targeted by
the fishery. There is a need to further review the catch
ranges within the fishery.

Harvest Strategy
The harvest strategy for barramundi in the Kimberley
Gillnet and Barramundi Managed Fishery in the
Kimberley region of Western Australia is based on a
constant commercial catch policy where the annual
commercial catches of barramundi are allowed to vary
within the target catch range, which is based on a
historical catch range during which the fishery was
stable and levels of exploitation were considered to be
sustainable.

Compliance
The KGBF is managed primarily through input
controls in the form of limited entry, seasonal and
spatial area closures and gear restrictions. There is a
closed season in which fishing is prohibited in the
KGBF. In the southern KGBF (west of Cunningham
Point, 123º08.23´ E longitude) the closure extends
from 1 December to 31 January the following year,
while in the northern section of the KGBF (east of
Cunningham Point) the closure extends from 1
November to 31 January the following year. There are
also limits on the length of net and mesh sizes to be
used in the fishery.

Recreational fishing activities are concentrated around
key population centres, with a seasonal peak in activity
during the dry season (winter months). Fish species in
the North Coast Bioregion are assigned bag and size
limits according to their ecological suite and the risk to
sustainability. The bag and size limits are species-
specific (e.g. barramundi) or species group specific
(e.g. mullet) to ensure that stock levels are maintained.
Recreational set and haul netting is prohibited in all
waters of the North Coast Bioregion with the exception
of haul netting in the waters of the Dampier
Archipelago (between Cape Preston and Cape
Lambert) with the following restrictions: haul nets
must not exceed 30 metres in length; mullet are the
only species to be retained and all other species must
be returned to the water.

Consultation
Fisheries undertakes consultation directly with
licensees on operational issues. Industry Management
Meetings are convened by the Western Australian
Fishing Industry Council (WAFIC), who are also
responsible for statutory management plan consultation
under a Service Level Agreement with Fisheries.
Consultation processes for the recreational fishing
sector are facilitated by Recfishwest under a Service
Level Agreement, although the Department undertakes
direct consultation with the community on specific
issues.

Consultation with non-fisher stakeholders is
undertaken in accordance with the Department’s
Stakeholder Engagement Guidelines.

Management Initiatives
The KGBF management plan was amended in June
2012 to modernise the fishery management
arrangements. New marine parks are currently being
developed for the Kimberley region.

EXTERNAL DRIVERS
The barramundi stocks utilising the Kimberley river
systems as nursery areas are expected to be reasonably
resilient to fishing pressure. However, the impact of
increasing exploitation from the charter and tourism
sectors on barramundi stocks needs to be monitored.

Furthermore, the smaller, isolated stocks along the arid
Pilbara coastline are likely to experience highly
variable recruitment due to environmental fluctuations
(e.g. the amount of rainfall).

In addition, the introduction of new marine parks (State
and Federal) across the Kimberley region has the
potential to concentrate fishing effort from multiple
sectors into those areas that remain open to fishing and
are easily accessible, increasing risks of local depletion
of barramundi and threadfin stocks.

Low risk.
OVERVIEW

A range of commercial and recreational fisheries target demersal scalefish resources in the North Coast Bioregion (NCB) of Western Australia. The major demersal fish species in the NCB (in order of gross tonnage) are; goldband snapper (*Pristipomoides multidens*), crimson snapper (*Lutjanus erythropterus*), red emperor (*Lutjanus sebae*), bluespotted emperor (*Lethrinus punctulatus*), saddletail snapper (*Lutjanus malabaricus*), rankin cod (*Epinephelus multinotatus*), browntripe snapper (*Lutjanus vitta*), rosy threadfin bream (*Nemipterus furcosus*), spangled emperor (*Lethrinus nebulosus*) and Moses’ snapper (*Lutjanus russelli*).

Commercial fisheries landing demersal scalefish resources in the NCB include the Northern Demersal Scalefish Managed Fishery (NDSMF) in the Kimberley subregion, and the Pilbara Demersal Scalefish Fisheries (PDSF) in the Pilbara subregion.

The PDSF include the Pilbara Fish Trawl (Interim) Managed Fishery (PFTIMF), the Pilbara Trap Managed Fishery and the Pilbara Line Fishery. The PDSF collectively use a combination of vessels, effort allocations (time), gear limits, plus spatial zones (including extensive trawl closures) as management measures. The main species landed by the fisheries in the Pilbara subregion are bluespotted emperor, red emperor, and rankin cod.

The permitted methods in the NDSMF (Area 2 – offshore area) includes handline, dropline and fish traps, but since 2002 it has essentially been a trap based fishery which uses gear time access and spatial zones as the primary management measures. The main species landed by this fishery in the Kimberley subregion are goldband snapper and red emperor. The inshore area of the NDSMF (Area 1) permits line fishing only, between the high water mark and a line approximating the 30 m isobath.

Recreational fishing activities in the NCB are mostly line-based fishing from private boats and charter vessels with effort concentrated around key population centres. The recreational fishery for demersal fish is managed through the use of input controls (e.g. recreational licenses, size limits) and output controls (e.g. bag and /or boat limits). The recreational and charter sectors do not catch significant quantities of most demersal scalefish species targeted by the commercial fisheries.

*Top 10 demersal species only from 2015/16 survey (Ryan et al. 2017)*
CATCH AND LANDINGS

Kimberley

Since 2008, NDSMF annual catches have exceeded 1,000 t. The 2016 catch of 1,173 t is within the acceptable catch range of 903–1,332 t (see Allowable Catch Tolerance Levels) for the fishery. Total catches in each zone (A, B and C) of the NDSMF were also within the range of those recorded since 2008. The majority of the catch is landed from Zone B, with a catch of 965 t in 2016.

Pilbara

The PDSF annual catches from the domestic fish trawl, trap and line fisheries peaked at 3,600 t in 1996. In 2008, following declining catch rates and relatively high levels of fishing mortality for red emperor in the western areas of the PFTIMF, effort was reduced for the PFTIMF in these areas. In 2016, the PDSF annual catches exceeded 2,000 t for the first time since effort reductions in 2008. In 2016, 71% (1,529 t) of the total commercial catches of demersal scalefish in the Pilbara (2,150 t) were landed by the trawl sector, with 23% (495 t) taken by the trap sector and 6% (126 t) taken by the line sector.

Total annual trawl catches have reduced from an average of 123,200 t in the period 1995-2004 to an annual average of 1,159 t from 2008-15, in response to the effort reductions imposed on the PFTIMF since 2008. The total demersal scalefish catch in the PFTIMF in 2016, despite having the same annual effort allocations as those imposed since 2008, slightly exceeded the acceptable catch range (i.e. 940-1,416 t). These increasing catch rates (combined with fishing mortality spawning biomass estimates) suggest effort reductions since 2008 have resulted in increased fish abundance and stock rebuilding in the PFTIMF.

The total annual trawl catch taken by the trap and line sectors have remained relatively consistent over the past decade, averaging 440 t and 100 t per year, respectively. The total catch of the trap and line fisheries were within the acceptable catch ranges in 2016 (i.e. 241-537 t for trap and 36-127 t for line).

The top 10 demersal species in the North Coast represented 77% of the total boat-based recreational catch (kept by numbers) in 2015/16. The estimated boat-based recreational harvest range for the top 10 demersal species in the North Coast was lower in 2015/16 (95% CI 34–47 tonnes compared with 48–69 in 2013/14 and 73–92 in 2011/12) (Ryan et al. 2017).

INDICATOR SPECIES

ASSESSMENTS AND STOCK STATUS

Kimberley (Sustainable-Adequate)

Due to the resource comprising a large number of species, indicator species have been selected from the suite of demersal scalefish (based on their inherent vulnerability, management importance and overall risk to sustainability) for assessing the status of the overall resource. The demersal indicator species for the Kimberley region are red emperor (Lutjanus sebae) and goldband snapper (Pristipomoides multidens).

A 2015 assessment of the two indicator species in the Kimberley estimated the spawning biomass of red emperor stock to be currently around the target level (1.33 \( BV \)). Similarly, the spawning biomass of the goldband snapper stock was estimated to be currently above the threshold level (which corresponds to \( BV \)).

Representative age structure samples of each indicator species in the Kimberley region were collected in late 2016 and early 2017, and will be processed and used to update the stock assessments in 2017/18. The life history parameters for these species are also currently being reviewed and updated to better inform the assessment model.

On the basis of the evidence provided above, the biological stocks are classified as sustainable-adequate.

Pilbara (Sustainable-Adequate)

Due to the resource comprising a large number of species, indicator species have been selected from the suite of demersal scalefish (based on their inherent vulnerability and overall risk to sustainability) for assessing the status of the overall resource. The three demersal indicator species for the Pilbara region are red emperor (Lutjanus sebae), rankin cod (Epinephelus multinotatus), and bluespotted emperor (Lethrinus punctulatus). The status of ruby snapper (Etelis sp) is also used as an indicator species for the offshore demersal scalefish resources targeted by the Pilbara Line Fishery. The stock status of indicator species are assessed periodically (~ every 5 years) using a weight-of-evidence approach that considers all available information as described above.

A 2016 assessment of the three indicator species in the Pilbara estimated the spawning biomass of red emperor stock to be currently above the threshold level (which corresponds to \( BV \)). The stocks of rankin cod, bluespotted emperor and ruby snapper are well above the target spawning biomass levels.

Representative age structure samples of indicator species in the Pilbara region collected in 2015 will be processed and used to update the stock assessments in 2017/18. The life history parameters for these species are also currently being reviewed and updated to better inform the assessment model and support MSC full assessment for the Pilbara trap fishery. On the basis of the evidence provided above, the biological stocks are classified as sustainable-adequate.

BYCATCH AND PROTECTED SPECIES INTERACTIONS

Kimberley Trap / Pilbara Trap

There is a limited quantity of non-retained bycatch in these fisheries. The most common bycatch species is the starry triggerfish (*Abalistes stellaris*), but the numbers taken are considered to pose a negligible risk to the sustainability of this species.

Using trap gear in continental shelf regions is very unlikely to interact with listed species. Previous video observations indicate that the potato cod (*Epinephelus tukula*), a totally protected species, can be present in high numbers at discrete locations within the fishery. However, potato cod rarely enter traps because most individuals encountered are large in size and girth which limits their capacity to pass through the entrance funnel into the traps. Negligible risk.

The Kimberley and Pilbara trap fisheries regularly capture sea snakes. In 2016, the Pilbara and Kimberley trap fisheries reported ~213 and ~26 sea snakes, respectively. Sea snakes are returned to the water alive. Low risk.

Pilbara Fish Trawl

Species of teleosts caught as bycatch by the trawl fishery are typically small bodied and/or short lived. Such species are considered less vulnerable compared to longer-lived teleost species based on their population production potential. Thus, the indicator species used in the weight-of-evidence stock assessments for the Pilbara demersal scalefish resources are considered to provide an adequate indication for similar or less vulnerable retained and bycatch species.

The use of Bycatch Reduction Devices (BRDs) has been mandatory in the PFTIMF since 2006. BRDs are highly effective in reducing reptile (turtles and sea snakes) bycatch. Bottlenose dolphin interactions with BRDs are rare (5.2 per 1,000 trawls) despite high levels of attendance and depredation during trawling. Loss of targeted teleosts through the BRD hatch is also rare (1.3% of fish during day trawls). Based on high levels of subsurface observer coverage in 2012 (60% of day trawls or 56% of day trawl hours), the subsurface expulsion of megafauna in poor condition was negligible (see Wakefield *et al.* 2014; Wakefield *et al.* 2016). Low-moderate risk.
The PFTIMF was re-accredited a Wildlife Trade Operation (WTO) under the Commonwealth of Australia’s Environmental Protection and Biodiversity Conservation Act 1991 (EPBC) for three years from mid-2014. This was extended until 30 May 2018. The accreditation included specific conditions around the observing, reporting and mitigation of endangered, threatened and protected species interactions. As such, an ongoing 12-month independent electronic observer program will be conducted during this accreditation period.

NORTH COAST DEMERSAL FIGURE 1.
Annual commercial catches of indicator species from the Kimberley and Pilbara demersal scalefish fisheries from 1993 to 2016.

HABITAT AND ECOSYSTEM INTERACTIONS
Kimberley Trap / Pilbara Trap and Line
As a result of the gear design, these fisheries have little impact on the habitat overall, although there may be some rare interactions with coral habitats which are not common in areas where the fisheries operate. The need to maintain relatively high levels of biomass for the species caught in this fishery to meet stock recruitment requirements results in a negligible risk to the overall ecosystem from the fishery. Hall and Wise (2011) demonstrated that there has been no reduction in either mean trophic level or mean maximum length in the finfish catches recorded within the Kimberley (i.e. no fishing down of the food web) over the past 30 years.
Pilbara Trawl

The PFTIMF is restricted to less than ~2% of the North West Shelf (NWS). Area 3 and the waters inside the 50 m isobath are permanently closed to fish trawling, Zone 1 is closed to fish trawling, and Area 6 has had no fish trawl effort allocation since 1998. Within the areas actually trawled, monitoring has indicated that approximately 10% of the sessile benthic fauna (e.g. sponges) are detached per year. Considering effort for the trawl fishery is at historically low levels and the effective area trawled within the managed areas has been greatly reduced, it is likely that the trawl fishery imposes a moderate risk to the small amount of habitat in the Areas open to trawling (~2% of NWS) but a negligible risk to the total habitat in the North West Shelf.

The PFTIMF operates with standard stern trawling gear (single net with extension sweeps) within an area previously trawled by foreign vessels. Previous research by CSIRO has suggested that the extensive Taiwanese pair Trawl Fishery caused a significant decrease in the biomass of finfish on the North West Shelf, and a change in species composition towards smaller (shorter lived) species. The current WA Fish Trawl Fishery, which developed when the fish stocks had begun to recover, uses a much larger mesh size and much lighter ground gear, and operates at lower exploitation rates and only in restricted parts of the continental shelf. At the present levels of catch and effort by the fish trawl, fish trap, and line fisheries, the broader effect on the trophic levels and community structure of the North West Shelf is considered to be at an acceptable level. Hall and Wise (2011) demonstrated that there has been no reduction in either mean trophic level or mean maximum length in the finfish catches recorded within the Pilbara (i.e. no fishing down of the food web) over the past 30 years and thus represents a low risk to the ecosystem.

SOCIAL AND ECONOMIC OUTCOMES

Social

Kimberley: Seven vessels fished in the 2016 fishing season, and at least 24 people (3-4 crew per vessel) were directly employed in the NDSMF. Approximately half the fish from this fishery are supplied to Perth metropolitan markets, while the other half is supplied to east coast metropolitan markets.

Pilbara: It is estimated that ~10 fishers on 2 vessels were directly employed during 2016 in the trawl sector, and 8 fishers on 3 vessels in the trap sector, and at least ~15 fishers on 5 vessels in the line sector. Overall, at least ~33 people (e.g. 3-4 crew per vessel) were directly employed in the PDSF.

Recreational fishing attracts many visitors to the North Coast Bioregion, particularly in inshore areas over the winter dry season (April – October). This provides employment through local charter fishing services and fishing tackle outlets around key population centres, as well as more remote charter operations offering wilderness fishing experiences in the north Kimberley region, including offshore locations such as the Rowley Shoals.

The annual estimated boat-based recreational fishing effort in the North Coast Bioregion was lower in 2015/16 (31,375 boat days, SE=2,414) compared with 2013/14 (45,604, SE=3,603) and 2011/12 (47,721, SE=3,778) (Ryan et al. 2017).

The North Coast Demersal Scalefish Resource provides a high social amenity to recreational fishing and diving and to consumers via commercial fish supply to markets and restaurants. There is currently a low level of risk to these values.

Economic

Kimberley: The NDSMF principally targets the high-value species such as the goldband snapper and red emperor resulting in an economic value of $5-10 million. The social amenity value is that this is an important asset locally.

Pilbara: The fish trawl demersal scalefish catch is dominated by lower-valued species such as bluespotted emperor and threadfin bream, and its value is estimated to be $1-5 million. For social amenity some of the species may be caught recreationally and/or there is some specific interest in the resource by the broader community. The fish trap and line catches are dominated by valuable species such as red emperor and goldband snapper, and the demersal scalefish catch from these sectors was estimated to have an economic value of $1-5 million and they also have social amenity value. For the line fishery the economic value is < $1 million and social amenity is low because there is little recreational fishing for these offshore species and no specific broader community interests.

GOVERNANCE SYSTEM

Allowable Catch Tolerance Levels (Acceptable)

Kimberley

For the 2016 calendar year, the total allowable effort was set at 986 standard fishing days in Zone B of the fishery, and 616 and 1,100 standard fishing days in Zone A and C of the fishery, respectively. At these levels of total effort and at recent catch rates, the total catch of the fishery is expected to be in the range of 903–1,332 t. The total 2016 catches were within the acceptable catch range.

Pilbara

The total catch of the trawl fishery slightly exceeded the acceptable catch range in 2016 despite having the same reduced annual effort allocations as those imposed since 2008. This increased catch represents an increase in stock abundance following nine years of reduced effort in the western trawl managed areas. The total catch of the trap and line fisheries were within the acceptable catch ranges in 2016.
Harvest Strategy

A harvest strategy for the North Coast Demersal Scalefish Resource is in development to support the full MSC assessments for the trap fisheries. It will provide a description of the objectives, performance indicators, reference levels, and associated control rules that articulate pre-defined, specific management actions designed to maintain the resource at target levels.

The harvest strategy focuses on the exploitation and stock status of the indicator species in the Kimberley and Pilbara demersal scalefish fisheries. These indicator species include red emperor and goldband snapper in the Kimberley, and red emperor, bluespotted emperor, and rankin cod in the Pilbara. Periodic assessments of selected non-indicator species are also occasionally undertaken to validate the indicator species approach and ensure that the status of other retained species remains at acceptable levels. The assessment and harvest strategies of these species are primarily based on estimates of spawning stock biomass (or an appropriate proxy for biomass), relative to internationally accepted target, threshold and limit reference levels.

The commercial sectors are managed primarily through input controls in the form of a total allowable effort allocation system via individually transferable effort allocations. The recreational and charter sector are primarily managed using size limits for some species, and daily bag and possession limits. Recreational fishers operating from a boat are required to have a current Recreational Fishing from Boat Licence (RFBL). Charter operators are required to have a Fishing Tour Operators Licence.

Compliance

The primary management measures of gear time usage and spatial zone access for North Coast trap and trawl fisheries are monitored and enforced using a satellite-based vessel monitoring system (VMS). The annual fishing effort capacity limits the amount of effort available in the fishery to achieve the notional target total allowable catch. Additional management measures include size limits, and limits on the numbers of fish that can be taken by individual recreational fishers and by recreational fishers fishing from boats.

Consultation

The Department undertakes consultation directly with licensees on operational issues. Industry Management Meetings are convened by the Western Australian Fishing Industry Council (WAFIC), who are also responsible for statutory management plan consultation under a Service Level Agreement with the Division. Consultation processes for the recreational fishing sector are facilitated by Recfishwest under a Service Level Agreement, although the Division undertakes direct consultation with the community on specific issues.

Consultation with non-fisher stakeholders is undertaken in accordance with the Department’s Stakeholder Engagement Guidelines.

Management Initiatives/Outlook Status

Kimberley

Age structure data for the indicator species were collected in late 2016 and early 2017 in order to revise the next assessment scheduled for 2017/18.

The Northern Demersal Scalefish Fishery Operators Guide to the Management Arrangements 2016 (DoF, 2016) was published in July 2016, and is a plain English guide to the management arrangements, designed to assist licence holders.

Pilbara

Age structure data for the indicator species were collected in 2015 in order to revise the next assessment schedule for 2017/18.

In 2016/17, the Department is collaborating with permit holders in the Pilbara Fish Trawl Interim Managed Fishery to adhere to the conditions of the re-accredited Wildlife Trade Operation approval; this will include a logbook validation program, through electronic monitoring.

In 2017/18, the Department will be working with the Commonwealth Department of Environment and Energy and Pilbara Trap licence holders to complete an assessment of the Pilbara Trap Fishery under the EPBC for export approval.

EXTERNAL DRIVERS

The Commonwealth’s North-west Marine Bioregional Plan incorporates the aim of introducing marine reserves, which are likely to contain areas closed to fishing. This has the potential to restrict access to fishing in parts of the North Coast Bioregion to all sectors, i.e. commercial, recreational and charter.

Under the Offshore Constitutional Settlement, commercial trawl vessels licensed by the Commonwealth may operate in waters outside of a line that represents the 200 m isobath as part of the North West Slope Trawl Fishery (NWSTF).

Climate change and climate variability has the potential to impact fish stocks in a range of ways including influencing their geographic distribution (e.g. latitudinal shifts in distribution). However, it is unclear how climate change may affect the sustainability risks to North Coast demersal fisheries.

Low risk.
REFERENCES

STATEWIDE LARGE PELAGIC FINFISH RESOURCE STATUS REPORT 2017
P. Lewis and R. Jones

OVERVIEW
The large pelagic resource is distributed throughout Western Australia (WA) and includes a range of tropical and temperate pelagic species. The three indicator species are Spanish mackerel (Scomberomorus commerson) and grey mackerel (Scomberomorus semifasciatus) representing the Tropical suite, and Samson fish (Seriola hippos) for the Temperate suite (DOF 2011).

Commercially the resource is predominantly accessed by the Mackerel Managed Fishery (MMF) in the North Coast (NCB) and Gascoyne Coast Bioregions (GCB) targeting Spanish mackerel. In the West Coast (WCB) and South Coast Bioregions (SCB) the major retained temperate species is Samson fish as bycatch (see relevant chapters for more details). The recreational fishery for large pelagic fish is dominated by Spanish mackerel with the majority of the catch for most species released (Ryan et al. 2017). For further details see the Statewide Large Pelagic Scalefish Resource Assessment Report and relevant species chapters in SAFS (2016).

CATCH AND LANDINGS

The commercial catch of Spanish mackerel by the MMF was 276 t in 2016 and has been 270-330 t since quotas were introduced in 2006 (Large Pelagic Finfish Figure 1a). The commercial landings of Amberjack (Seriola dumerili), Cobia (Rachycentron canadum) and Golden Trevally (Gnathanodon speciosus) in the NCB were 17, 12, and 11t, respectively, with other large pelagic species in the NCB and GCB all <10 t in 2016. In the WCB and SCB only the annual catch of Samson fish was >10 t, at 25 t in 2016.

The top 10 pelagic scalefish species (or species groupings) in 2015/16 represented 99% of the total resource catch (kept by numbers). The estimated recreational harvest range for the top ten pelagic species in the North Coast was mostly steady in 2015/16 (95% CI 21–31 tonnes compared with 23–41 in 2013/14, but lower than 40–61 in 2011/12) (Ryan et al. 2017). A similar or higher amount was released.

LARGE PELAGIC FINFISH FIGURE 1.

a) Annual statewide commercial catch (t) for the three large pelagic indicator species and b) Annual catch rate of Spanish mackerel in the MMF, by management zone, with dotted line around each representing +/- standard errors.
INDICATOR SPECIES ASSESSMENTS AND STOCK STATUS

Spanish mackerel (Sustainable-Adequate)

Spanish mackerel are fast growing, moderately long lived (to 26 years), grow to a large size (to 40 kg), have high fecundity and have a young age at sexual maturity (less than 2 years) (Mackie et al. 2003) indicating resilience to fishing pressure. Spanish mackerel in WA are likely a shared biological stock with the Northern Territory.

Following management changes in 2006, catch and effort throughout the MMF have been relatively stable. The catch rates in the Kimberley and Pilbara management zones are stable or increasing (Large Pelagic Finfish Figure 1b), suggesting that the overall spawning stock is stable or increasing. The catch rate in the southern Gascoyne-South zone has declined after a peak in 2014 when catches were high, possibly due to the effects of the marine heatwave (Pearce 2011). The annual charter boat operators’ catch of Spanish mackerel in WA has been 17-37 t since 2003 with 34-61% released/discarded. The estimated boat-based recreational harvest range of Spanish Mackerel in the North Coast was steady in 2015/16 (95% CI 12–22 t) compared with 16–32 t in 2013/14, but lower than 27–47 t in 2011/12 (Ryan et al. 2017). The decline in catch for the NC and GCB can be partly attributed to the 20-35% decline in recreational effort, particularly during the months from April-August, when higher catches of these species occur. In addition, for the WCB the decline in Spanish mackerel catch in 2015/16 (704 kept by number, SE=243) compared with 2013/14 (2,376, SE=425) and 2011/12 (2,927, SE=443) is likely due to lower water temperatures reducing the abundance of the species in the southern extent of their range. The spawning biomass of Spanish mackerel in Western Australia is therefore considered to be sustainable-adequate.

Grey mackerel (Sustainable-Adequate)

Grey mackerel in WA likely constitute a single biological stock (Newman et al. 2010). Grey mackerel are fast growing, relatively short lived (to 12 years) and have a young age at sexual maturity (less than 2 years) (Cameron and Begg 2002) indicating resilience to fishing pressure.

Grey mackerel catches in the MMF since 2000 have been relatively low at 3.5 to 24 t (Large Pelagic Finfish Figure 1a). In 2016 the WA catch was 14 t, with 9 t taken in the Pilbara being the highest since 2004. This level of catch is well below the TACC (60 t for each of the three management areas) for grey mackerel. The low levels of catch are likely to reflect the gear limitations (line only) and limited targeting of the species in the MMF. The annual charter boat operators’ catch of grey mackerel in WA has been 1 t or less since 2003. The estimated recreational catch of Grey Mackerel was been <1 tonne in 2011/12, 2013/14 and 2015/16, although the uncertainty for this species is high (Ryan et al. 2017). On the basis of the evidence provided above, the breeding stock is classified as sustainable-adequate.

Samson fish (Sustainable-Adequate)

Samson fish in WA is likely to constitute a shared biological stock with South Australia. The species are moderately long lived (to 29 years), can grow to a large size (40 kg+), mature at four years of age, undertake large scale movements and are able to withstand capture from deep water (Rowland 2002), indicating resilience to fishing pressures.

In 2016 the statewide commercial catch of Samson fish was 25 t, split evenly between the WCB and SCB. Since 2008 catches have been at historically low levels of <45 t (Large Pelagic Finfish Figure 1a), due primarily to reductions in the WCB since management changes in the West Coast Demersal Scalefish Interim Managed Fishery (WCDSIMF) and Temperate Demersal Gillnet and Demersal Longline Managed Fishery (TDGDLMF). Over the past 5 years the catches of Samson fish have been 7-16 t in each of the South Coast open access line fishery, WCDSIMF, and TDGDLMF. The species is targeted recreationally with the majority (>70%) discarded. The annual charter boat operators’ catch of Samson fish in WA has been 10-17 t since 2010 with 68-76% released/discarded.

The estimated boat-based recreational catch of Samson fish was steady in 2015/16 (1,962 kept by number, SE=258) compared with 2013/14 (2,769, SE=393) and 2011/12 (2,143, SE=249), with a similar high release rates of 74-84% (Ryan et al. 2017). On the basis of the evidence provided above, the breeding stock is classified as sustainable-adequate.

BYCATCH AND PROTECTED SPECIES INTERACTIONS

Bycatch: The non-mackerel bycatch taken by the MMF are predominantly other large pelagic species which annually contribute <1 t (2016). Thus, there is negligible risk to the breeding stocks of other finfish species, by fishers targeting the large pelagic resource.

Protected species: Due to the selectivity of the fishing methods used by commercial and recreational fishers targeting large pelagic species, and the rarity of interactions with protected species by the MMF there is considered to be a negligible risk to listed species.

HABITAT AND ECOSYSTEM INTERACTIONS

Habitat: The surface and midwater troll fishing methods used by the MMF and recreational fishers targeting large pelagic species does not impact with the benthic marine environment (DEWA 2009). On longer fishing trips the vessels may anchor but the impacts from anchoring are considered to be minimal, as anchors are set in naturally dynamic environments.
Ecosystem: The amount of Spanish mackerel removed from the ecosystem is unlikely to impact trophic interactions, as mackerel are generalist carnivores and consume a wide range of fish and invertebrate species from both pelagic and demersal habitats (Mackie et al. 2003). Therefore, the fishery is considered to be a low risk to both habitat structure or ecosystem interactions.

SOCIAL AND ECONOMIC OUTCOMES

Social
Approximately 33 people were directly employed in the MMF during the 2016 mackerel fishing season, primarily from May - November. The estimated participation rate for recreational fishing in the population of WA is 29.6% in 2013/14 (DoF 2015). Recreational boat based surveys indicate that Spanish mackerel is one of the highest retained species in the NCB and GCB (Ryan et al. 2017) while other iconic large pelagic species are targeted but discarded in high numbers. The large pelagic resource provides a moderate social amenity to recreational fishing and diving and to consumers via commercial fish supply to markets and restaurants. There is currently a negligible level of risk to these values.

Economic
In 2016, the estimated value (to fishers) of the Spanish mackerel annual catch was level 2, approximately $2.5 million. The value of the annual catch of grey mackerel and other Large Pelagic species was estimated at less than $500,000. There is currently a low level of risk to this return.

GOVERNANCE SYSTEM

Governing Legislation
Mackerel Managed Fishery Management Plan 2011 (Management Plan): The MMF is the only WA commercial fishery licensed to land mackerel species. The MMF is controlled by Individual Transferrable Quota system (ITQs) to control catch and has annual catch tolerance ranges established. The recreational and charter fishers are managed by output controls including daily bag limits for the resource.

Annual Catch Tolerance Levels (Acceptable)
The target commercial catch range for Spanish mackerel in the MMF is 246-430 t. The annual catch tolerance ranges for the three areas of the MMF are Kimberley Area is 110 – 225 t, the Pilbara Area is 80 – 126 t and Gascoyne/West Coast Area is 56 – 79 t. The 2016 Spanish mackerel catch of 191 t in the Kimberley is within the range while the catches of 71 and 14 t in the Pilbara and Gascoyne/West Coast, respectively, are below the tolerance ranges but have been for most years since 2006 and the catch rates are stable so deemed acceptable.

Harvest Strategy (Under development)
For Spanish mackerel the current method of assessment focuses on analysis of catch and catch rates (Levels 1 and 2), with previous analyses having been used to determine the Tolerance Levels and TACC. A draft harvest strategy has been developed for the MMF using reference levels for the catch rates of Spanish mackerel which have been derived from data collected over a reference period (2006 to 2011) when fishing was considered sustainable (DoF in prep).

Compliance
All boats in the MMF are fitted with an Automatic Location Communicator (ALC) which enables the Department to monitor the fleet using a Vessel Monitoring System (VMS). Masters of an authorised boat within the MMF are also required to submit logbook records and catch and disposal records (CDRs). The Department also undertakes vessel inspections at sea to ensure fishing is being undertaken in accordance with the governing legislation (e.g. gear requirements, catch reporting).

Consultation
Management Meetings are held every two years between the Department and MMF licensees, in conjunction with the Industry Consultation Unit of the Western Australian Fishing Industry Council (WAFIC). Consultation on recreational fishing regulations or relevant commercial management changes is undertaken through the peak body, Recfishwest. Consultation with non-fisher stakeholders is undertaken in accordance with the Department’s Stakeholder Engagement Guidelines.

Management Initiatives (Stable)
In August 2015, the MMF received an exemption from the export controls of the EPBC for a period of ten years.

EXTERNAL DRIVERS
Many large pelagic species experience annual variations in recruitment strength and adult movement due to environmental fluctuations. The changing marine environment off the WA coast may benefit some tropical species in the southern parts of their range, as seen during the marine heatwave of WA when Spanish mackerel distribution shifted southwards (Pearce et al. 2011). Other external factors on the fishery include the petroleum industry restricting access to fishing grounds in some parts of the Pilbara Area, the high proportion of discarded fish and the unknown level of mortality rates and in some areas the increased mortality of hooked and discarded large...
pelagic species by depredation. Finally, the past two Indian Ocean Tuna Commission (IOTC) assessments of the Spanish mackerel catch have determined the species is overfished and subject to overfishing. However, this outcome does not apply to the Western Australian component of the northern Australian stock which is distinct from that of other parts of the Indian Ocean. However, these external factors constitute an overall low risk to WA’s Large Pelagic resource, with possible impacts varying among individual species.

Cameron D, and Begg G. 2002. Fisheries biology and interaction in the northern Australian small mackerel fishery. Final report to Fisheries Research and Development Corporation. Projects 92/144 & 92/144.02, Department of Primary Industries, Queensland.

OVERVIEW

The Western Australian pearl oyster fishery is the only remaining significant wild-stock fishery for pearl oysters in the world. It is a quota-based, dive fishery, operating in shallow coastal waters along the north coast bioregion and targets the silver lipped pearl oyster (*Pinctada maxima*). The fishery is currently managed under the *Pearling Act 1990* and uses output controls in the form of a total allowable catch (TAC) divided up into individually transferable quotas (ITQs). Fishing for *P. maxima* is one component of the pearling industry’s activities with seeding and grow-out of pearl oysters to produce pearls.

This fishery has been accredited for export under the EPBC Act for a period of ten years (re-assessment in 2025) and has achieved MSC certification. Further information can be sourced from Hart *et al.* (2016).

Governance

MSC certification. The ARMA will subsume the *Pearling Act 1990*.

| External Driver | Moderate - High Risk |

CATCH AND LANDINGS

In 2016, catch was taken in Zones 1, 2, and 3 and the number of wild-caught pearl oysters was 541,260 comprising of 490,804 culture shells and 50,456 MOP shells (Pearl Figure 1). Total effort was 19,699 dive hours (Pearl Figure 1), a decrease of 4% from the 2015 effort of 20,455 hours. Of this total effort, 18,411 hours was focused on culture shell fishing, and the remaining 1,288 hours was applied to MOP fishing. Fishing continued in Zone 1 for the third year, after a hiatus from 2008 to 2013, however it was only a minor proportion (<1%) of the catch. In 2016, the number of wild-caught pearl oyster shell in Zone 1 was 4,594 comprising only culture shells.
PEARL FIGURE 1:
Total pearl shell catch (all areas) and effort (Zone 2/3). ‘Culture shells’ are pearl oysters ≥100 and <175 mm shell length, ‘MOP shells’ are pearl oysters ≥175 mm.

INDICATOR SPECIES ASSESSMENTS AND STOCK STATUS

Zone 1 Pinctada maxima (Sustainable - Adequate)

Based on the information and analyses available, the current risk level for pearl oysters in Zone 1 is estimated to be LOW. The low risk reflects the minimal levels of fishing mortality. All the lines of evidence are consistent with a low level of risk, hence the overall Weight of Evidence assessment indicates the status of the Zone 1 pearl oyster stock is adequate and that current management settings are maintaining risk at acceptable (low) levels.

Zone 2 Pinctada maxima (Sustainable - Adequate)

Based on the information and analyses available, the current risk level for pearl oysters in Zone 2 is estimated to be moderate. The moderate risk reflects the controlled levels of fishing mortality. Some lines of evidence are inconsistent with a low level of risk, in particular, the breaching of the threshold reference points in the standardised catch rate data series. This breach however, has been clearly shown to be a function of lower than average recruitment years, rather than evidence of broodstock depletion. Preliminary data on catch rates in 2017 confirm the predicted increase in abundance to above target levels. Overall, the weight of evidence assessment indicates the status of the Zone 2 pearl oyster stock is adequate and that current management settings are maintaining risk at acceptable (moderate) levels.

Zone 3 Pinctada maxima (Sustainable - Adequate)

Based on the information and analyses available, the current risk level for pearl oysters in Zone 3 is estimated to be LOW. The low risk reflects the minimal levels of fishing mortality. All the lines of evidence are consistent with a low level of risk, hence the overall Weight of Evidence assessment indicates the status of the Zone 3 pearl oyster stock is adequate and that current management settings are maintaining risk at acceptable (low) levels.

BYCATCH and PROTECTED SPECIES INTERACTIONS

Divers have the ability to target pearl oysters of choice (species, sizes and quality of P. maxima). Pearl oysters brought to the vessel after hand collection are young and have relatively little epiphytic growth (fouling organisms). A small number of over-sized or under-sized pearl oysters are returned to the substrate. Therefore bycatch impact is negligible.

There is no interaction between the pearl oyster fishing operation and protected species (Hart et al., 2016). Negligible risk.

HABITAT and ECOSYSTEM INTERACTIONS

The fishery removes only a small proportion of the biomass of pearl oysters on the fishing grounds and is considered to have negligible impact on the food chain in the fishing area. Pearl divers have minimal contact with the habitat during fishing operations. The main habitat contact is by pearl oysters held in mesh panels.
on holding sites following capture. However, these sites cover a very small proportion of the habitat and the activity concerned is unlikely to cause any lasting effect.

Similarly, the pearl farming operation, which uses longline systems in areas of high tidal flow to culture pearls, has limited impact on the environment. Physical effects are limited to static anchoring systems in typically sand/mud habitats. Environmental management research has demonstrated that pearl farming has negligible impacts on habitat and environment.

SOCIAL AND ECONOMIC OUTCOMES

Social effects (Low Risk)
Pearl oyster fishing vessels operate from the Lacepede Islands north of Broome to Exmouth Gulf in the south. The number of vessels in the fishing fleet has been slowly reducing from 16 in 1997 (overall), mostly due to increased fleet efficiency and increased reliance on hatchery-produced pearl oysters. In 2009, with the negative impact of the Global Financial Crisis (GFC) on the industry, only two vessels fished. The number of vessels fishing in 2016 was six. Most vessels presently operate 10 – 14 crew for the fishing of pearl oysters between March and August each year. These vessels also support pearl oyster operations and a number of other pearl oyster farm functions throughout the year.

Prior to the GFC, the pearling industry provided employment for approximately 500 people in the northern coastal regions, including in the operation of the pearl oyster farms. However the impact of the GFC resulted in a substantial reduction in personnel employed in the pearling industry and current full-time FTEs is estimated around 300.

Economic (High Risk)
A precise estimate of the total industry value is difficult to achieve, owing to the variable time lags that occur between harvesting and sale to offshore buyers, and the costs incurred in marketing before sales take place. Based on information provided by the industry, the value of cultured pearls and by-products in 2016 was considered to be approximately $71 million, which is 9% lower than 2015 when it was $78 million.

GOVERNANCE SYSTEM

Annual Catch Tolerance Levels (Acceptable)
TAC (612,550 pearl oysters in 2016) to be caught in 14,071-20,551 dive hours.
Commercial catch (pearl oysters) for season 2016: 541,260 oysters at 19,699 dive hours.
Both the catch and effort levels were acceptable.

Harvest Strategy (Formal)
The harvest strategy for *P. maxima* is a constant exploitation approach, operationalised through an annual TAC, divided into ITQs. The TAC is set in proportion to overall stock abundance. Harvest control rules determine the TAC according to the relation of predicted catch rates in comparison to target, threshold, and limit reference levels (DoF, 2016).

The control rules in place ensure that the catch is reduced when predicted recruitment is low, in order to provide increased protection to the stock, but also allows the catch to be raised in years when predicted abundance is high.

Compliance
The pearling industry is highly regulated by the Department. Access to the wildstock pearl oysters is limited to holders of the relevant pearling (wildstock) licence, and attached quota. Similarly, companies producing hatchery-reared pearl oysters must hold the appropriate hatchery licence(s), pearlling (seeding) licence- hatchery quota if seeding is occurring, health certification and transport approvals when appropriate and pearl oyster farm leases. Applications for a pearl oyster farm lease are reviewed and approval by the Department. The total area a company holds is linked to the pearl oyster quota and stock holding held by that company.

Consultation
The Department undertakes consultation directly with the Pearl Producers Association (PPA) and licensees on operational issues. Formal license holder engagement is convened by the Western Australian Fishing Industry Council (WAFIC) under a Service Level Agreement with the Department. The stock assessment and sustainable harvest levels are discussed by the Stock Assessment Working Group (SAWG) and with licence holders, the PPA and WAFIC at the Annual Management Meeting (AMM) each year. SAWG advice, a summary of discussions at the AMM and a PPA letter are provided to the Director General when determining the annual TAC for the pearl oyster fishery.

Consultation with non-fisher stakeholders is undertaken in accordance with the Department’s Stakeholder Engagement Guidelines.

Management Initiatives
This fishery has been accredited for export under the EPBC Act for a period of ten years (re-assessment in 2025) and has recently been certified under the MSC certification process. The announcement of MSC accreditation is expected in mid-2017. Further information can be sourced from Hart *et al.* (2016).

A new State Act of Parliament to ensure the sustainability and management of all WA’s aquatic biological resources was introduced into Parliament in
2015-16. The Aquatic Resource Management Act 2016 will replace both the Fish Resources Management 1994 and the Pearling Act 1990. The Department is reviewing the current legislative framework ahead of the introduction of the new Act to transition the pearl oyster fishery and activities associated with pearl culture.

EXTERNAL DRIVERS
External influences include other activities and factors that occur within the pearl oyster fishery that may or may not impact on the productivity and sustainability of fisheries resources and their ecosystems. The main external influences included here are catch from other fisheries, environmental factors (i.e. cyclones and climate variation), market influences, tourism, liquid natural gas (LNG) exploration, disease and introduced species. Pearl oysters were ranked as a moderate-high risk to climate change effects.

SEA CUCUMBER RESOURCE STATUS REPORT 2017
A. Hart, D. Murphy, C. Syers and P. Kalinowski

OVERVIEW
The Western Australian Sea Cucumber fishery is a commercial only fishery, with animals caught principally by diving, and a smaller amount by wading. It targets two main species; sandfish (Holothuria scabra) and redfish (Actinopyga echinites). Fishing occurs in the northern half of the State from Exmouth Gulf to the Northern Territory border and is managed through input controls including limited entry, maximum number of divers, species-dependent minimum size limits, and gear restrictions. This fishery is undergoing assessment for Marine Stewardship Council certification.

LANDINGS

In 2016, both species were targeted, with a total catch of 93 t (Sea Cucumber Figure 1). This catch comprised of 91 t of sandfish (*H. scabra*) and 2 t of deepwater redfish (*A. echinites*). In 2015 only sandfish was targeted with a catch of 37 t, an increase of 150% on this species and the highest catch in 13 years. The industry has generally adopted a rotational fishing strategy for both sandfish and redfish with limited catch taken for either species in 2012 and 2013.
INDICATOR SPECIES ASSESSMENTS AND STOCK STATUS

Kimberley Sandfish (Sustainable-Adequate)
Based on the information and analyses available, the current risk level for Kimberley sandfish was estimated to be moderate. This is consistent with previous assessments of the fishery. Therefore the overall Weight of Evidence assessment indicates the status of the Kimberley sandfish stock is adequate and that current management settings are maintaining risk at acceptable (moderate) levels.

Pilbara Sandfish (Sustainable-Adequate)
Based on the information and analyses available, the current risk level for Pilbara sandfish was estimated to be low. Therefore the overall Weight of Evidence assessment indicates the status of the Pilbara sandfish stock is adequate and that current management settings are maintaining risk at low levels.

Pilbara Redfish (Sustainable-Adequate)
Based on the information and analyses available, the current risk level for Pilbara redfish was estimated to be moderate. This is consistent with previous assessments of the fishery. Therefore the overall Weight of Evidence assessment indicates the status of the Pilbara redfish stock is adequate and that current management settings are maintaining risk at acceptable (moderate) levels.

BYCATCH and PROTECTED SPECIES INTERACTIONS
Given the hand only method of fishing no bycatch is taken by the fishery and there are no known protected species interactions. Negligible risk.

HABITAT and ECOSYSTEM INTERACTIONS
Divers collect sea cucumber as they drift over the bottom of the seabed; there is minimal impact on the habitat as divers are highly selective in their fishing effort and no fishing gear or lines contact the seabed. This fishery harvests only a small amount of sandfish and redfish per annum. The effect from this harvesting on the rest of the ecosystem, given that the catch is spread over a wide region, would be insignificant. Due to the toxins present in their body tissues, it is highly unlikely they are a major diet for higher-order predators. Negligible risk.

SOCIAL AND ECONOMIC OUTCOMES

Social (Low Risk)
Generally a vessel employs 4 to 6 crew with one of those a master, a deckhand and remaining divers. Additional individuals are employed for the processing of the product. These activities are mostly located in the Northern Territory and Victoria where the fishing fleet is based.

Economic (Low Risk)
The estimated annual value for 2016 was $300,000 based on an average product price of $3.00 per kg live weight and total catch of 94 tonnes. This is a farm-gate value and supports a substantial processing and value adding sector.

GOVERNANCE SYSTEM

Annual Catch Tolerance Range (Acceptable)
Commercial: Sandfish (Kimberly): 0-100 t; Sandfish (Pilbara): 0-80 t; Redfish (Pilbara): 0-150 t
The catch of sea cucumber was within the tolerance ranges for all species. This indicates the status of sea cucumber stocks is adequate and that current management settings are maintaining risk at acceptable levels.

Harvest Strategy
The key considerations informing the harvest strategy for the sea cucumber resource in Western Australia are its geographical isolation, status as a developing fishery, the spatially discrete nature of the resource, and the intrinsic vulnerability of sea cucumber stocks when effort is difficult to constrain. Consequently the performance indicators include area and species-specific indices, such as quantity of harvest (catch) as well as density of stocks (standardised catch rates). The Sea Cucumber fishery is currently undergoing an MSC certification process and, as part of this process, the existing harvest strategy is being reviewed and updated. The revised harvest strategy is expected to include a new series of performance indicators, threshold levels, and control rules.

Compliance
There are no current issues.

Consultation
Industry Management Meetings are convened by the Western Australian Fishing Industry Council (WAFIC), under a Service Level Agreement with the Department.
Management Initiatives (MSC Assessment and Review Planned)

A review of the sea cucumber fishery is planned for 2017. It is anticipated that this review will result in the fishery transitioning from Exemption based to a formal management arrangement in 2018. The species-specific information on catch and effort from the daily logbook, implemented in 2007, has facilitated the development of species-specific performance indicators and these will be refined as more information arises. The WA Sea Cucumber Fishery is currently undergoing an MSC assessment and certification process.

EXTERNAL DRIVERS

The remoteness of the currently fished stock and the large tidal ranges where it occurs are natural barriers to uncontrolled expansion of fishing. Marine park planning has to date restricted this fishery from general use zones of some MPAs. Currently, lack of experienced fishers and suitable vessels is restricting catch to low levels.

Climate change could have positive or negative impacts on sea cucumber populations. It has been reported that higher sea temperatures will have a positive effect i.e. higher production and yields given the expected faster growth rates leading to larger sizes and increased fecundity.

Low risk.

NORTH COAST CRAB FISHERY RESOURCE STATUS REPORT

OVERVIEW

Blue swimmer crabs (BSC) are targeted by the Pilbara Developmental Crab Fishery within inshore waters around Nickol Bay using hourglass traps. Recreational fishers for this species use drop nets or scoop nets, with diving for crabs becoming increasingly popular. Management arrangements for the commercial and recreational fisheries include minimum size, protection of breeding females, seasonal closures with effort controls for the commercial fishery (Johnston et al., 2015).

Mud crabs (MC) are harvested by the Kimberley Developing Mud Crab fishery using crab traps between Broome and Cambridge Gulf and Aboriginal Body Corporate Commercial Mud Crab Exemption holders. There is also a small recreational fishery for mud crabs.

CATCH AND LANDINGS

Commercial Sector
The total commercial catch of blue swimmer crabs and mud crabs in the North Coast Bioregion for 2016 was 36.9 t. The catch of blue swimmer crabs decreased 27% from that taken in 2015. The North Coast catch accounts for 7% of the state total commercial blue swimmer crab catch of 487 t for 2016.

The catch of mud crab for the Kimberley Developing Mud Crab Fishery represents the entire mud crab catch landed in WA in 2016. The catch in 2016 was approximately 96% lower than 2015 primarily due to the cessation of fishing by one operator. In 2016 the majority of catch was recorded as green mud crab, while a small proportion was recorded as brown mud crab.

Recreational Sector
The estimated boat-based recreational catch of blue swimmer crab in the North Coast represented 4% of the statewide boat-based recreational catch (kept by numbers) in 2015/16. The estimated boat-based recreational harvest range for blue swimmer crab in the North Coast was steady in 2015/16 (95% CI 1–3 tonnes compared with 2–6 in 2013/14 and 2–5 in 2011/12) (Ryan et al., 2017).

INDICATOR SPECIES ASSESSMENTS AND STOCK STATUS

Blue Swimmer Crabs (Sustainable-Adequate)
Catch rates from the Pilbara crab trap fishery provide an index of abundance to assess fishery performance. Crab trap catch rates increased steadily during exploratory fishing from 2001-2003 (North Coast Crab Figure 1) along the Pilbara coast. The increase in catch rate can be attributed to improvements to fishing gear, vessels and fisher knowledge. Favourable environmental conditions may have led to a significant increase in catch rates (1.6-1.8 kg/traplift) from 2004 to 2006, before returning to longer-term mean catch rates of 0.7 -1.0 kg/traplift between 2007 and 2012. (North Coast Crab Figure 1). Catch rate increased significantly in 2013 and 2014 (1.8 -1.9 kg/traplift) but declined to 1.1 kg/traplift in 2015.

The fishery recorded a mean nominal catch rate of 0.8 kg/traplift for 2016. Although this represented a 27% decrease from 2015, it was above the preliminary harvest strategy threshold of 0.6 kg/traplift, indicating there should be adequate egg production under typical environmental conditions. Therefore the breeding stock is considered sustainable-adequate.
Annual commercial trap catch per unit effort (CPUE) (kg/traplift) for the Pilbara Developmental Blue Swimmer Crab (*Portunus armatus*) fishery since 2000.

**Mud Crab (Sustainable-Adequate)**

Four species of mud crab (*Scylla* spp.) have been identified in the Indo-West Pacific region, of which the green mud crab (*Scylla serrata*) and brown mud crab (*Scylla olivacea*) occur in Western Australia (Keenan *et al.*, 1998). The green mud crab is predominantly found in estuarine habitats in north-western Australia from the Northern Territory border to Shark Bay. The brown mud crab has a more restricted distribution limited to northern embayments, with most catches from King Sound, 200 km northwest of Broome.

The minimum legal size at first capture is 150 mm CW for green mud crab (*Scylla serrata*) and 120 mm CW for brown mud crab (*Scylla olivacea*). These are set well above the size at first maturity of 90-120 mm CW for green and 86-96 mm CW for brown mud crab fisheries in the North Coast Bioregion. Consequently, breeding stock levels are expected to be adequate to maintain stocks in all current fishing areas under normal environmental conditions.

Catch rates between 2012 and 2015 fluctuated between 0.4 and 0.9 kg/traplift, with a nominal catch rate of 0.4 kg/traplift reported in 2016. This represents a significant (35%) decline from last year (0.6 kg/traplift), and is below the (draft) harvest strategy threshold of 0.5 kg/traplift and only slightly above the limit of 0.35 kg/traplift (North Coast Crab Figure 2). The significant decrease in fishing effort from 220 fisher days in 2015 to 50 fisher days in 2016 is the most likely cause of the decline, as fishing efficiency declined due to a lack of continuous fishing and the introduction of a new operator to the fishery.

Catch and effort has been limited to such a low level in recent years that based on the relatively small impact of commercial operations, the wide distribution of the species throughout the region, and the minimum legal size set well above size at maturity, the risk to sustainability has been considered to be negligible and currently the breeding stock is considered *adequate*. The stock is classified as *sustainable* and the level of fishing is considered *acceptable*. Nevertheless, considering the proximity of the 2016 catch rate to the limit reference level, catch, effort and catch rate is being monitored closely in this fishery during the 2017 season.
BYCATCH and PROTECTED SPECIES INTERACTIONS

Blue Swimmer Crab
The shift from using set nets to traps in most blue swimmer crab fisheries has resulted in a substantial reduction in bycatch from dedicated crab fishing. Pots are purpose-designed to minimise the capture of non-target species and are therefore an inefficient way to capture fish, the majority of which are able to escape through the entrance gaps when the pot is soaking or being hauled. Small numbers of fish are infrequently captured in crab pots, but the fishers are not permitted to retain them. The low number of fish caught and returned by crab fishers is considered to pose a negligible risk to these stocks.

Discarded bycatch from trawl fisheries taking crabs as a by-product is dealt with in the status reports that are specific to each trawl fishery.

The crab trap longline system used in the targeted crab fisheries has little possibility of interacting with listed species. The fishery is conducted in a manner that avoids mortality of, or injuries to, endangered, threatened or protected species and avoids or minimises impacts on threatened ecological communities and is considered a negligible risk to these stocks.

As mud crab traps are purpose built to target mud crab species and are set for relatively short periods of time, the possibility of causing harm to listed species is minimal and a negligible risk.

HABITAT and ECOSYSTEM INTERACTIONS

Blue Swimmer Crab: Fishing with traps results in limited habitat disturbance, with only minor dragging of traps on the bottom occurring during trap retrieval. Sand and associated biota do not get brought to the surface in commercial blue swimmer crab traps, as the mesh used on traps is sufficiently large to allow the escape of any sand-dwelling macro-benthos. Although seagrasses are occasionally brought to the surface with the trap, the infrequent nature of this occurrence, and the small amount of living seagrass removed, results in minimal habitat damage, posing a low risk to benthic habitat.

Mud Crab: Trap fishing in the shallow waters of associated mangrove tidal creeks and near shore embayments results in limited habitat disturbance. The large mesh size prevents capture of benthic organisms and only minor dragging of traps on the sea floor occurring in trap retrieval. The sheltered shallow mangrove environment is protected from wind and waves where the majority of traps are deployed, resulting in minimal habitat damage, posing a low risk to benthic habitat. As the commercial take of blue swimmer and mud crabs represents a relatively small portion of the biomass, which is effectively renewed annually and subject to high levels of natural variation in abundance, secondary food chain effects are likely to be minimal in these fisheries and are a low risk to the ecosystem.
SOCIAL AND ECONOMIC OUTCOMES

Social
Blue Swimmer Crab
North Coast blue swimmer crab fisheries provide a high social amenity to recreational fishing and diving and to consumers via commercial crab supply to markets and restaurants. During 2016, four people were employed as skippers and crew on vessels fishing for blue swimmer crabs along the Pilbara coast. Additional employment for several workers has been created in Point Samson through the development of post-harvest processing of the crab catch.

Mud Crab
The Kimberley mud crab fishery provides a high social amenity to recreational fishing and to consumers via commercial mud crab supply to markets and restaurants. Commercial fishers travel vast distances due to the remoteness of their operations and stay in the vicinity for several weeks before returning to unload catch. In this scenario crabs are frozen and generally sold to local markets although live product may also be sold at premium prices. There were two commercial operators that fished during 2016, with effort concentrated between April and October.

Economic
The estimated gross value of product (GVP) for the crab fishery within the Northern Bioregion for 2016 was approximately $218 k (Level 1 <$1million).

Blue Swimmer Crabs: The average beach price for trap caught blue swimmer crabs across all Western Australian fisheries for 2016 was around $5.41/kg. The crab catch from the Pilbara region was sold through local and interstate markets.

Mud Crabs: The average beach price for green (uncooked) mud crabs in the Kimberley for 2016 was around $36.43/kg (value is based on a small proportion of total catch from an individual processor). Aboriginal corporations may also trade and barter product adding value to the local communities that cannot be estimated.

GOVERNANCE SYSTEM

Annual Catch Tolerance Levels
Pilbara BSC: n/a
Kimberley Mud Crab: n/a
Blue Swimmer Crab
While no formal tolerance range has been developed for the Pilbara Developmental Crab Fishery current effort levels in the fishery are considered acceptable. Fishing effort in this region is limited by very hot weather experienced during the summer months, which generally restricts fishing effort to between April and November.

Mud Crab
The mud crab fishery is currently being fished at low/precautionary levels due to the low number of fishers operating in the fishery and relatively low effort across a large area of the Kimberley.

Harvest Strategy
The breeding stock of crab fisheries are protected by effort control, legal minimum size (127–130 mm) well below the size at maturity (86–98 mm carapace width), and seasonal closures in some fisheries.

Blue Swimmer Crabs: Preliminary harvest strategy has been determined for the Pilbara Developmental Crab Fishery where the primary performance indicator is nominal annual commercial catch rates, specifically within the Nickol Bay area due to the majority of fishing historically occurring in this area. The reference period is between 2005 and 2011 as defined by the period when the developing fishery status commenced but following the period of 2001-2004 when exploratory fishing occurred.

As the indicator was above the threshold in 2016, no changes to the management occurred for the 2017 season.

Mud Crabs: A preliminary harvest strategy has been determined for the Kimberley Developing Mud Crab Fishery where the primary performance indicator is nominal annual commercial catch rate. The reference period is between 2006 and 2011 as defined by when the developing fishery status commenced under exemptions.

As the indicator in 2016 was below the threshold but above the limit, the fishery will be closely monitored to ensure adequate stock protection in the 2017 and 2018 seasons.

Compliance
Current risks to enforcement are low for North Coast Bioregion crab fisheries.

Consultation
The Department undertakes consultation directly with licensees on operational issues and processes and is responsible for the statutory management plan consultation. Industry Management Meetings are convened by the Western Australian Fishing Industry Council (WAFIC), who are also responsible for statutory management plan consultation under a Service Level Agreement with the Fisheries. Consultation processes are now facilitated by Recfishwest under a Service Level Agreement although Fisheries undertakes direct consultation with the community on specific issues. Consultation with non-fisher stakeholders is undertaken in accordance with the Department’s Stakeholder Engagement Guidelines.
Management Initiatives

From 1 May 2013, mud crab exemption holders were permitted to retain bycatch of other Portunid crabs for a two year trial period which ended on 30 April 2015. Negligible catches of blue swimmer crabs were retained during this trial. A minimum size limit of 135 mm for blue swimmer crabs was imposed, consistent with the size limit used in the Pilbara Developmental Crab Fishery. No limits were placed on the number of blue swimmer crabs which could be retained. It is proposed that permitting the retention of blue swimmer crabs as bycatch will be incorporated into future exemptions for the mud crab fishery. A new Management Plan is being developed for the mud crab fishery which is expected to commence in 2018. The Management Plan is proposed to permit the take of Portunid crabs (including blue swimmer crabs).

An increase of 200 traps (total 600 traps) was allocated in 2016 for Pilbara Developmental Crab Fishery, with the traps able to be used across two vessels. As a precautionary measure to this increase in traps numbers, an annual season closure between 15 August and 15 November (inclusive) was implemented to protect berried and mated pre-spawning female. A new Management Plan is being developed for the Pilbara developmental crab fishery which is expected to commence in 2018.

EXTERNAL DRIVERS

Levels of recruitment to many of the crab fisheries fluctuate considerably. These are considered most likely due to environmental influences (e.g. water temperature) both on spawning success and larval survival through to recruitment. The relationship between environmental factors, recruitment and catch is being further evaluated as data becomes available. The climate change implications associated with these environmental variables are also under consideration. Blue swimmer crabs were rated a high risk to climate change due to their sensitivity to water temperature changes.
